Abstract

In November 1969, Dana Scott formulated a mathematical program to construct the first non-degenerate, purely mathematical model (D_∞) for Alonzo Church’s untyped λ -calculus. He formally detailed this in his landmark 1972 paper *Continuous Lattices*, providing the foundational justification for denotational semantics. However, Scott’s initial 1972 framework relied on dense, abstract point-set topology, which remained an intimidating barrier for computer scientists seeking a practical tool for representing programming language semantics.

When Scott delivered his lectures at Oxford in 1980—subsequently published as *Lectures on a Mathematical Theory of Computation* (Technical Report PRG-19)—he made an intentional, systematic pivot. The 1980 lectures focused on discrete information presented as *domains*. This more discrete presentation was intended to be more accessible to computer scientists without training in point-set topology and lattice theory.

This Lean 4 formalization covers every element of PRG-19, including all exercises. We strive to avoid law of the excluded middle. We check axioms throughout, so if a proof seems to unavoidably require law of the excluded middle, that will be shown in the axiom check.

1 Introduction

To make domain theory accessible, the 1980 monograph introduces three key conceptual and structural shifts:

1.1 The Information-Theoretic Ordering

In contrast to the topological open sets of 1972, the 1980 lectures treat domains strictly as partially ordered sets (posets) representing states of incomplete information. An element within a domain is framed as a “partial description” of a computation. The ordering relation ($\sqsubseteq$) is explicitly interpreted as approximation: $x \sqsubseteq y$ means x contains less information than, or approximates, y .

1.2 Neighbourhood Systems and Finite Approximations

To bypass the complexities of continuous geometric spaces, Scott introduced **Neighbourhood Systems**. He recognized that real-world computing machines only ever interact with finite, checkable tokens of data. In this framework, an infinite computational process (such as an

infinite stream or a complex recursive function) is defined as the limit of an ever-tightening sequence of these finite neighbourhoods. This shifted the underlying mathematics away from general topology and toward formal logic and order theory.

1.3 Solving Universal Recursive Domain Equations

While Scott’s 1969 discovery was a specialized solution to the specific self-referential equation $D \cong [D \rightarrow D]$, the 1980 monograph provides a universal factory blueprint. Scott uses inverse limits over Directed-Complete Partial Orders (CPOs) to solve arbitrary recursive domain equations. This generalized framework allowed computer scientists to give rigorous mathematical meaning to standard recursive computer data structures, such as lists, trees, and stream types.

1.4 Formalization Target: Consolidating “Scott Domains”

This Lean 4 artifact formalizes the mathematical objects that these 1980 lectures ultimately standardized for the computer science community, known today as **Scott Domains**. A Scott Domain is characterized as a poset that is: 1. **Directed-Complete (CPO)**: Every directed subset has a least upper bound, ensuring that infinite computations have well-defined limits. 2. **ω -algebraic**: Every element in the domain can be represented as the supremum of a countable set of compact (finite) elements, mirroring how infinite data is built from finite tokens. 3. **Consistently Complete**: If any two pieces of information do not outright contradict each other, they possess a join (least upper bound), allowing consistent computation streams to merge safely.

1.5 A caveat: topology gives way to recursion-theoretic bookkeeping, not to simplicity

Scott’s 1980 pivot (§1–3 above) trades point-set topology for order theory and finite tokens, and for most of the monograph that trade genuinely simplifies the formalization: neighbourhood systems, approximable maps, and the domain-equation solutions of Lectures I–VI are combinatorial objects with comparatively little topological machinery behind them. But it would be a mistake to read this as “the 1980 lectures are elementary throughout.” From Lecture VII onward, Scott’s subject is **computability in domains** — effectively given presentations, computable elements, computable maps — and this content is intrinsically recursion theory, not topology. Mechanizing it honestly means mechanizing recursion theory, and that turns out to be the more expensive half of this formalization by a wide margin, for a reason specific to this project’s foundational choices rather than to Scott’s mathematics:

Mathlib’s own recursion theory (`Nat.Primrec`, `Primrec`, `Partrec`, `ComputablePred`) is unusable here because its correctness lemmas are proved via tactics (`grind`, `lia`, the `Nat.unpair_pair simp set`) that route through `Classical.choice`, which would silently taint every downstream computability result in this project with an axiom this formalization otherwise avoids (see the choice discipline below). The practical consequence is that **Recursive.lean** — a *from-scratch*, choice-free recursion theory (primitive-recursive `Nat.pair/unpair` round-trips, `Nat.sqrt` correctness, recursively-decidable predicates and their closure lemmas, course-of-values recursion via fuel-indexed tables) — is now **4,000+ lines**, roughly **9× the size of Basic.lean** (450 lines), the file containing the actual domain-theoretic definitions (neighbourhood systems, elements, subsystems) that this whole formalization is nominally *about*. A representative data point: Exercise 8.15’s “computable elements correspond to effectively presented domains” half needed perhaps 30–40 lines of genuine neighbourhood-system reasoning (an intersection dichotomy, a filter-closure invariant), sitting on top of 250+ lines encoding finite binary trees as `Nat.pair`-coded naturals and proving their evaluation is primitive recursive — a fact any computability textbook states in one sentence, made expensive here purely because

Lean’s `Nat.pair`/`Nat.unpair` are not kernel-reducible and Mathlib’s off-the-shelf apparatus is off-limits by this project’s own discipline.

In short: the 1980 lectures did succeed in retiring topology as the dominant technical overhead, but Lecture VII onward replaces it with a different overhead — recursion-theoretic encoding and course-of-values bookkeeping — that is, in this formalization, actually the larger of the two by line count. This is a cost of the choice-free discipline adopted below, not a property of Scott’s mathematics; a formalization willing to inherit `Classical.choice` through Mathlib’s recursion theory would find Lecture VII’s exercises considerably shorter.

1.6 Chapter inclusion hierarchy (Lean imports)

Each node is a lecture (Scott chapter) at the point its Lean modules are first introduced. An edge $A \rightarrow B$ means some module belonging to lecture B has a direct `import` of a module belonging to lecture A (transitive imports through intermediate lectures are *not* drawn). Edge labels count those direct import sites. This is the dependency picture relevant to splitting the monograph into separate arXiv papers.

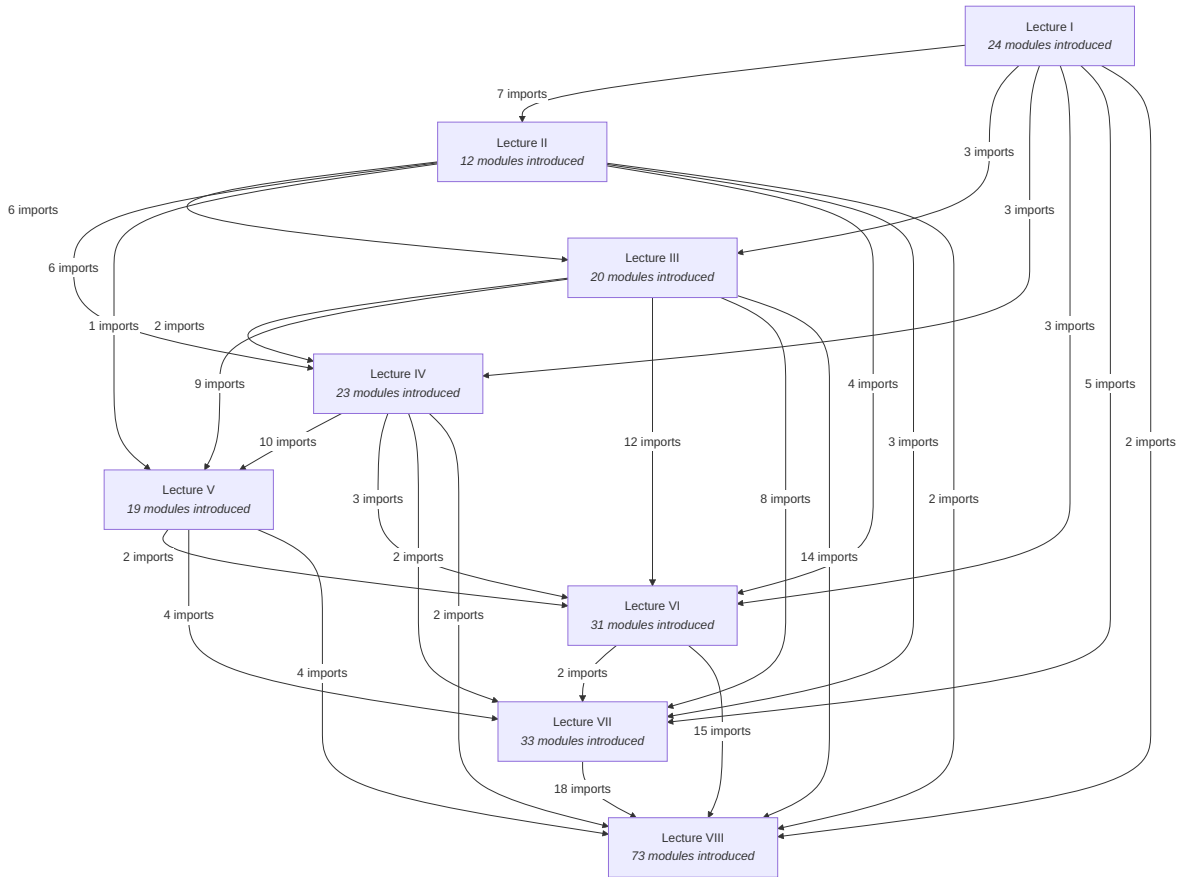

Figure 1: Chapter inclusion hierarchy (Lean imports).

2 Methodology

This section records the proof-engineering conventions of the formalization—the parts of the development workflow that are of general academic interest, distilled from the project’s internal

handoff notes.

2.1 Source material and inventory

The primary source is Dana Scott’s *Lectures on a Mathematical Theory of Computation* (Oxford, 1980; Technical Report PRG-19). OCR transcriptions live in `sources/PRG19_vision.md`; the structured inventory of every numbered Definition, Theorem, Example, and Exercise—with formalization status and proof notes—is maintained in this document (`arxiv.md`). Each item is keyed to Scott’s original numbering and cross-linked to its Lean module. Status values distinguish **Pass** (mechanized, builds green, zero `sorry`), **Partial** (substantial core done; documented gaps remain), **Not Yet**, and **Deferred** (Lecture VIII and items beyond the current formalization frontier).

2.2 Neighbourhood systems as the uniform substrate

Following Scott’s 1980 pivot away from point-set topology, domains are encoded uniformly as **neighbourhood systems**: a master set Δ , a family $\mathcal{D}$ of neighbourhoods (filters on Δ), and domain elements as filters over $\mathcal{D}$. Approximable maps, products, function spaces, sums, and fixed-point combinators are built on this substrate in `Basic.lean`, `Approximable.lean`, `Product.lean`, and `FunctionSpace.lean`. Positive systems (Exercise 1.19) and effectively given presentations (Definition 7.1) are layered on top when Scott’s exercises demand computability content.

2.3 Custom recursion theory (Lecture VII)

For **effectively given** domains Scott requires two index relations to be *recursively decidable*: (i) intersection equality $X_n \cap X_m = X_k$, and (ii) consistency $\exists k. X_k \subseteq X_n \cap X_m$. Rather than `mathlib`’s `Computable/ComputablePred` development—which pulls `Classical.choice` through tactics such as `grind`, `lia`, and `Nat.unpair_pair`—we rebuilt the needed slice in `Recursive.lean`:

- `RecDecidable p :=  $\exists f, \text{Nat.Primrec } f \wedge \forall n, p\ n \leftrightarrow f\ n = 1$` (and the binary/ternary pair-codings `RecDecidable2`, `RecDecidable3`);
- choice-free correctness for `Nat.sqrt`, `Nat.pair/unpair`, and primitive-recursive `+/*`;
- closure lemmas (`RecDecidable.of_iff`, `.comp`, `.and`, `.or`, `.not`, bounded $\forall/\exists$ via `bForallFn/bExistsFn`);
- r.e. layers `REPred/REPred2` as projections of decidable relations.

Target axiom footprint for data constructions and core proofs: $\subseteq \{\text{propext}, \text{Quot.sound}\}$. `Classical.choice` is permitted only for genuinely unavoidable **Prop-level** steps (e.g. classical case splits on membership in an arbitrary system) and is always called out in proof notes. Each completed module is audited with `#print axioms`.

2.4 Incremental proof development

Large exercises are decomposed into small, revert-safe sessions rather than monolithic proofs. The inventory’s granularity — how far a single numbered item is split into lettered or numbered sub-goals before being discharged — was set by hand, session by session, rather than by a fixed rule. Some exercises (Exercise 7.22’s fifteen-plus sub-items above are the extreme case) were deliberately drilled down into small, independently provable pieces *before* any Lean was written, because the informal statement was large enough that a single monolithic proof attempt would have wasted effort on a failing whole-proof search. Others were left as a single inventory row even though the underlying Lean proof has considerable internal structure, because the statement

was small enough that further decomposition would only add bookkeeping without changing how the proof was actually attacked. The deciding factors were pragmatic and varied by session: the size and combinatorial shape of the informal statement, the point at which further upfront planning showed diminishing returns, and how much compute budget seemed prudent to spend on decomposition versus a direct proof attempt. Consequently, the depth of decomposition visible in the inventory does not track a formal complexity metric of Scott’s original exercises; it is an artefact of session-by-session engineering judgment and should be read as such, not as a claim about which parts of PRG-19 are intrinsically harder to formalize.

3 Chronological Formalization Narrative

Below is the chronological narrative of the formalization, organized step-by-step using Dana Scott’s original numbering system from the PRG-19 monograph.

3.1 Lecture I: Domains by Neighbourhoods

Definition 1.1

- **Mathematical Target:** `NeighborhoodSystem (mem, master, master_mem, inter_mem, sub_master)`
- **Lean File:** `Scott1980/Neighborhood/Basic.lean`

`NeighborhoodSystem  $\alpha$` bundles a membership predicate `mem : Set  $\alpha$  → Prop` (Scott’s $X \in \mathcal{D}$), the master neighbourhood `master` (Scott’s Δ , kept as a field rather than hard-wired to `Set.univ`, for fidelity to the Δ notation), and Scott’s two conditions: (i) `master_mem` ($\Delta \in \mathcal{D}$) and (ii) `inter_mem` (consistent binary intersections stay in $\mathcal{D}$, the witness $Z \subseteq X \cap Y$ passed explicitly). A fourth field `sub_master` records Scott’s standing assumption $\mathcal{D} \subseteq \mathcal{P}(\Delta)$ (every neighbourhood $X \subseteq \Delta$); it is what gives the principal filter $\uparrow X$ its top element Δ (Def 1.7) and underlies $\perp = \uparrow \Delta$ (Def 1.8). Each finite example supplies it as `fun _ => Set.subset_univ _` (their `master` is `Set.univ`). Scott’s recursive **convention** for the finite intersection $\bigcap_{i < n} X_i$ is the `def interUpTo (0 ↦  $\Delta$ ,  $n+1 \mapsto \text{interUpTo } n \cap X_n)$` ; **Factoids 1.1a/1.1b** are its two defining equations, both `rfl`.

Factoid 1.1a

- **Mathematical Target:** `interUpTo, interUpTo_zero ( $\bigcap_{i < 0} X_i = \Delta$ )`
- **Lean File:** `Scott1980/Neighborhood/Basic.lean`

Factoid 1.1b

- **Mathematical Target:** `interUpTo_succ ( $\bigcap_{i < n+1} X_i = (\bigcap_{i < n} X_i) \cap X_n$ )`
- **Lean File:** `Scott1980/Neighborhood/Basic.lean`

Theorem 1.1c

- **Mathematical Target:** `interUpTo_mem` (extend (ii) to finite seqs) + `consistent_iff_interUpTo_mem` (`consistency  $\iff \bigcap \in \mathcal{D}$`); aux `Consistent, interUpTo_subset`
- **Lean File:** `Scott1980/Neighborhood/Basic.lean`

Example 1.2

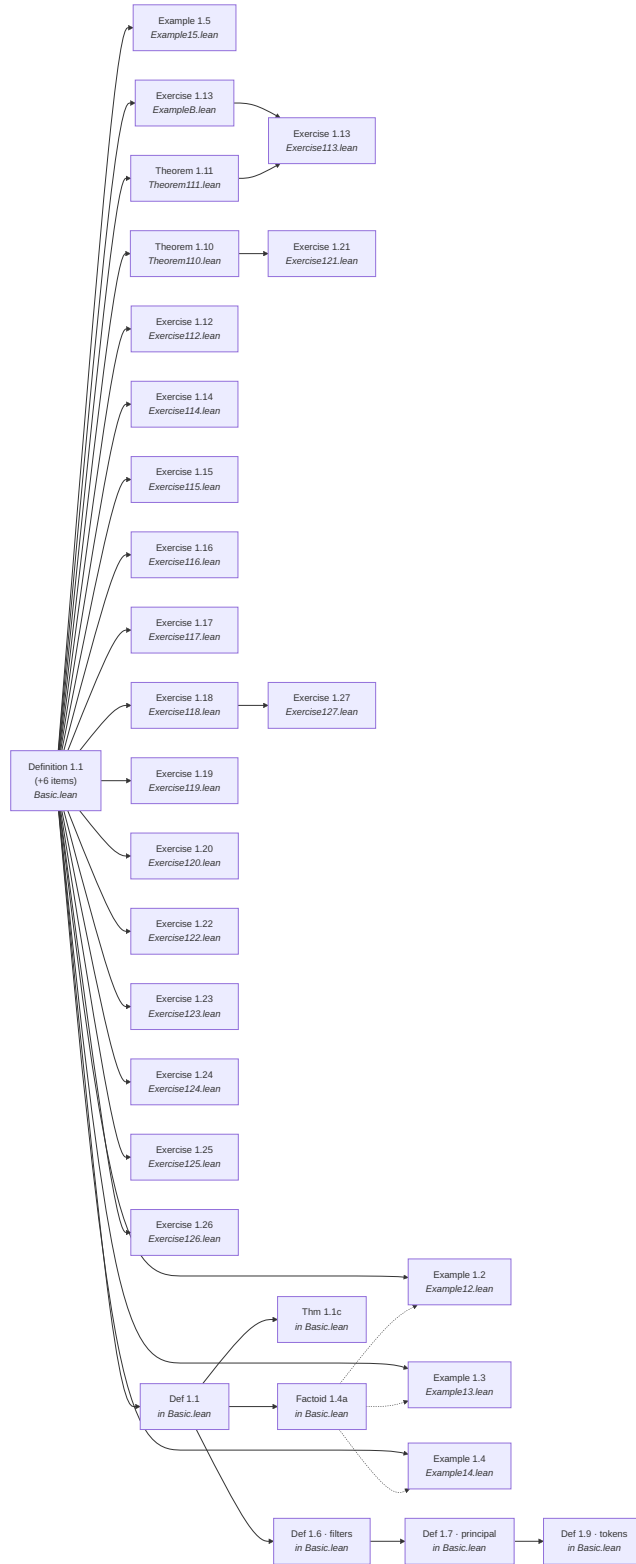

Figure 2: Lean module dependencies for Lecture I: Domains by Neighbourhoods.

- **Mathematical Target:** $\Delta=\{0,1\}$, $\mathcal{D}=\{\{0,1\},\{0\},\{1\}\}$; `neighborhoodSystem`, `element_classification` (exactly 3 filters), `bot_is_unique_partial` (one partial element)
- **Lean File:** — (see proof notes)

Scott’s first worked example: $\Delta = \{0,1\}$ (`Token := Fin 2`, `master := Set.univ`), $\mathcal{D} = \{\Delta, \{0\}, \{1\}\}$. We build `neighborhoodSystem : NeighborhoodSystem Token` — the only real obligation is condition (ii), discharged by `inter_eq` (the nine pairwise intersections each reduce to Δ , $\{0\}$, $\{1\}$, or $\emptyset$ via `master_inter/inter_master/Set.inter_self/zero_inter_one`), the $\emptyset$ case being impossible since a witness $Z \subseteq \emptyset$ would force $\emptyset \in \mathcal{D}$ (`not_mem_empty`).

The mathematical payoff is the **element classification** (`element_classification`): every filter is one of exactly three — `bot` = $\{\Delta\}$, `elemZero` = $\{\Delta, \{0\}\}$, `elemOne` = $\{\Delta, \{1\}\}$. The argument: a filter x either contains $\{0\}$ (then `up_mem+inter_mem` force $x = \text{elemZero}$; it cannot also contain $\{1\}$ since $\{0\} \cap \{1\} = \emptyset \notin \mathcal{D}$), or $\{1\}$ (symmetric), or neither (then $x = \text{bot}$). Hence `bot_is_unique_partial`: $\perp$ is the sole *partial* element, with `bot_lt_elemZero`, `bot_lt_elemOne` placing the two total elements strictly above it — exactly Scott’s “there is only one partial element”. Being a concrete finite computation it leans on `Mathlib.Tactic (fin_cases/simp)`, so its footprint is the classical [`propext`, `Classical.choice`, `Quot.sound`]; the constructive guarantee is reserved for the §1 *core* in `Basic.lean`.

Example 1.3

- **Mathematical Target:** $\Delta=\{0,1,2\}$, $\mathcal{D}=\{\{0,1,2\},\{1,2\},\{2\}\}$ (linear); `neighborhoodSystem`, `element_classification` (exactly 3 filters), `bot_lt_elemTwelve`, `elemTwelve_lt_elemTwo`, `elemTwo_maximal` (linear chain; token 2 total)
- **Lean File:** — (see proof notes)

Scott’s second worked example: $\Delta = \{0,1,2\}$ (`Token := Fin 3`, `master := Set.univ`), $\mathcal{D} = \{\Delta, \{1,2\}, \{2\}\}$ — a **linear chain** under reverse inclusion (more information = smaller set). We build `neighborhoodSystem : NeighborhoodSystem Token`; condition (ii) is discharged by `inter_eq` with only **three** outcomes (Δ , $\{1,2\}$, $\{2\}$) — every pairwise intersection is nested, so there is no empty-intersection case (contrast Example 1.2’s nine-case analysis).

The element classification (`element_classification`) yields exactly three filters in a linear chain: `bot` = $\{\Delta\}$, `elemTwelve` = $\{\Delta, \{1,2\}\}$, `elemTwo` = $\{\Delta, \{1,2\}, \{2\}\}$. The argument follows the same “case on minimal non-master neighbourhood” pattern as 1.2: if $\{2\} \in x$ then $x = \text{elemTwo}$; else if $\{1,2\} \in x$ then $x = \text{elemTwelve}$; else $x = \text{bot}$. Order lemmas `bot_lt_elemTwelve`, `elemTwelve_lt_elemTwo`, and `elemTwo_maximal` capture Scott’s narrative: approximation proceeds in **two steps** to the total element (token 2); tokens 0 and 1 are not total (they appear in larger neighbourhoods but do not determine filters); the direction of approximation is **unique** (no branching). Unlike 1.2 (one partial, two total), 1.3 has **two partial** elements and **one total**. Footprint [`propext`, `Classical.choice`, `Quot.sound`].

Example 1.4

- **Mathematical Target:** depth-2 binary tree $\Delta=\{\Lambda,0,1,00,01,10,11\}$; subtrees as neighbourhoods; `neighborhoodSystem`, `element_classification` (exactly 7 filters), `branch_bot_lt_elemZero/elemOne`, `elemZero_lt_elem00/01`, `elemOne_lt_elem10/11`, `four_leaf_elemXY_maximal` (first branching; 4 total elements)
- **Lean File:** — (see proof notes)

Scott’s third worked example and the first with **branching**: the depth-2 binary tree $\Delta = \{\Lambda, 0, 1, 00, 01, 10, 11\}$ (`Token := Fin 7`, with $\Lambda=0, \dots, 11=6$), neighbourhoods the subtrees $\mathcal{D} = \{\Delta, \text{left}=\{0,00,01\}, \text{right}=\{1,10,11\}, \{00\}, \{01\}, \{10\}, \{11\}\}$ — encoded as

$\text{left}=\{1,3,4\}$, $\text{right}=\{2,5,6\}$, and the four leaf singletons. Condition (ii) reduces to the “nested-or-disjoint” table: of the 49 pairwise intersections, each is again a neighbourhood or $\emptyset$. Rather than search, `inter_eq` rewrites $X \cap Y$ to its canonical value via a complete `simp` only set of the 24 distinct intersection lemmas (both orders) plus `master_inter/master/Set.inter_self`, so the matching disjunct closes by `rfl` — deterministic and fast (the naive 49×8 first ladder times out). The $\emptyset$ outcomes are inadmissible in `inter_mem` because a witness $Z \subseteq \emptyset$ would force $\emptyset \in \mathcal{D}$ (`not_mem_empty`).

The payoff is the **seven-filter classification** (`element_classification`): the bottom $\perp=\{\Delta\}$, two branch partials `elemZero`= $\{\Delta, \text{left}\}$ / `elemOne`= $\{\Delta, \text{right}\}$, and four total leaf filters `elem00`, ..., `elem11`. The proof cases on the minimal non-master neighbourhood: a leaf in `x` pins the total filter (`mem_leafXY_imp`, using that distinct leaves and cross-branch neighbourhoods intersect to $\emptyset$); otherwise `left/right` membership gives a branch partial, else $\perp$. The order lemmas realize the **tree with choice**: `bot_lt_elemZero/elemOne` (two incomparable partials above $\perp$), `elemZero_lt_elem00/01`, `elemOne_lt_elem10/11` (each partial below its two leaves), and `elemXY_maximal` for the four leaves (each leaf filter is maximal — a total element). Contrast the prior examples: 1.2 is a fork at the bottom (one partial, two total), 1.3 a linear chain (two partial, one total), and 1.4 a genuine tree (three partial, four total) where branching encodes the choice in extending a partial sequence. Footprint [`propext`, `Classical.choice`, `Quot.sound`].

Factoid 1.4a

- **Mathematical Target:** `NestedOrDisjoint + NeighborhoodSystem.ofNestedOrDisjoint`: “*nested-or-disjoint*” $\implies$ neighbourhood system (the “very special circumstance” of 1.2–1.4); choice-free
- **Lean File:** `Scott1980/Neighborhood/Basic.lean`

Scott’s “very special circumstance” after Examples 1.2–1.4 is the predicate `NestedOrDisjoint`
`mem :=  $\forall X Y, \text{mem } X \rightarrow \text{mem } Y \rightarrow X \subseteq Y \vee Y \subseteq X \vee X \cap Y = \emptyset$` . The constructor `NeighborhoodSystem`
`mem master master_mem hnd` then discharges condition (ii) without choice by casing on `hnd`:
if $X \subseteq Y$ then $X \cap Y = X$ (`Set.inter_eq_left.mpr`) so the intersection is `mem` by `hX`; symmetrically for $Y \subseteq X$; and if $X \cap Y = \emptyset$ the consistency witness $Z \subseteq X \cap Y = \emptyset$ gives $Z = \emptyset$ (`Set.subset_empty_iff`), so $X \cap Y = \emptyset = Z \in \mathcal{D}$. This is the uniform reason Examples 1.2 (fork), 1.3 (chain) and 1.4 (tree) are neighbourhood systems. Footprint [`propext`, `Quot.sound`].

Example 1.5

- **Mathematical Target:** $\Delta=\{0,1,2,3\}$, $\mathcal{D}$ = all non-empty subsets; `Example15.neighborhoodSystem` (`mem X := X.Nonempty`), `mem_iff_nonempty`
- **Lean File:** — (see proof notes)

$\Delta = \{0,1,2,3\}$ (`Token := Fin 4`) with $\mathcal{D}$ = all **non-empty** subsets (`mem X := X.Nonempty`, `master := Set.univ`). Condition (ii) is immediate and choice-free: a non-empty witness $Z \subseteq X \cap Y$ makes $X \cap Y$ non-empty (`obtain ⟨z, hz⟩ := hZ`; `exact ⟨z, hZsub hz⟩`). **Factoid 1.5a** (`consistent_iff_inter_nonempty`) is Scott’s remark that “sets are consistent iff they have a non-empty intersection”: reusing the `Basic Consistent/interUpTo` infrastructure, a prefix is consistent ($\exists Z, Z.\text{Nonempty} \wedge Z \subseteq \bigcap$) iff $\bigcap_{\{i < n\}} X_i$ is non-empty ($\rightarrow$ shrinks the witness, $\leftarrow$ takes the intersection as its own witness). Notably this example needs **no fin_cases/decide** and audits to [`propext`] (system) / [`propext`, `Quot.sound`] (Factoid 1.5a) — a fully constructive contrast to the finite Examples 1.2–1.4.

Factoid 1.5a

- **Mathematical Target:** in 1.5: `consistent_iff_inter_nonempty` (consistent $\iff$ non-empty intersection); $\mathcal{D}$ is a system

- **Lean File:** — (see proof notes)

$\Delta = \{0,1,2,3\}$ (Token := Fin 4) with $\mathcal{D}$ = all **non-empty** subsets (mem X := X.Nonempty, master := Set.univ). Condition (ii) is immediate and choice-free: a non-empty witness $Z \subseteq X \cap Y$ makes $X \cap Y$ non-empty (obtain $\langle z, hz \rangle := hZ$; exact $\langle z, hZsub hz \rangle$). **Factoid 1.5a** (consistent_iff_inter_nonempty) is Scott’s remark that “sets are consistent iff they have a non-empty intersection”: reusing the Basic Consistent/interUpTo infrastructure, a prefix is consistent ($\exists Z, Z.Nonempty \wedge Z \subseteq \bigcap$) iff $\bigcap_{i < n} X_i$ is non-empty ($\rightarrow$ shrinks the witness, $\leftarrow$ takes the intersection as its own witness). Notably this example needs **no fin_cases/decide** and audits to [propext] (system) / [propext, Quot.sound] (Factoid 1.5a) — a fully constructive contrast to the finite Examples 1.2–1.4.

Factoid 1.5b

- **Mathematical Target:** limitFamily, SeqEquiv, limitFamily_eq_iff: limit-family $x = \{Z \in \mathcal{D} \mid \exists n, X_n \subseteq Z\}$ equal $\iff$ sequences equivalent; choice-free
- **Lean File:** — (see proof notes)

The prose motivating Definition 1.6: a descending sequence $\langle X_n \rangle$ of neighbourhoods determines the limit family $\text{limitFamily } X = \{Z \in \mathcal{D} \mid \exists n, X_n \subseteq Z\}$, and two sequences are SeqEquiv (“equally deep”) when $\forall m, \exists n, X_n \subseteq Y_m$ and $\forall n, \exists m, Y_m \subseteq X_n$. $\text{limitFamily_eq_iff}$ proves $\text{limitFamily } X = \text{limitFamily } Y \leftrightarrow \text{SeqEquiv } X \ Y$ (assuming each term is a neighbourhood): $\rightarrow$ feeds each $Y_m \in \text{limitFamily } Y$ through the family equality to extract $X_n \subseteq Y_m$ (and symmetrically); $\leftarrow$ chains $Y_m \subseteq X_n \subseteq Z$ (and symmetrically) via transitivity. Antitonicity of the sequences is not needed for the criterion itself. Footprint [propext, Quot.sound].

Definition 1.6

- **Mathematical Target:** Element (filter: sub, master_mem, inter_mem, up_mem) + Element.ext; domain $|\mathcal{D}|$
- **Lean File:** — (see proof notes)

Element V is Scott’s filter (Def 1.6): a membership predicate $\text{mem} : \text{Set } \alpha \rightarrow \text{Prop}$ with $\text{sub} (x \subseteq \mathcal{D})$, $\text{master_mem} (\Delta \in x)$, inter_mem (closed under $\cap$), and up_mem (upward closed in $\mathcal{D}$). Mirroring InfoSys.Element, the early helper Element.ext (membership-equality $\implies$ equality, proved by rcases on both structures + funext/propext, not congr) keeps the PartialOrder instance (Def 1.8’s approximation order $x \sqsubseteq y \iff x \subseteq y$) choice-free: le_antisymm is just Element.ext fun X => $\langle h1 \ X, h2 \ X \rangle$. Footprint [propext, Quot.sound].

Definition 1.7

- **Mathematical Target:** principal $\uparrow X = \{Y \in \mathcal{D} \mid X \subseteq Y\}$ (mem_principal); the finite elements
- **Lean File:** — (see proof notes)

Scott’s *principal filter* $\uparrow X = \{Y \in \mathcal{D} \mid X \subseteq Y\}$ is principal ($hX : V.\text{mem } X$) : V.Element, with $\text{mem } Y := V.\text{mem } Y \wedge X \subseteq Y$. The four filter laws: sub is the first projection; $\text{master_mem} = \langle V.\text{master_mem}, V.\text{sub_master } hX \rangle$ (this is where the new sub_master field earns its keep — $X \subseteq \Delta$); inter_mem combines Set.subset_inter (from $X \subseteq Y_1, X \subseteq Y_2$) with one use of V.inter_mem, taking X itself as the consistency witness $X \subseteq Y_1 \cap Y_2$; up_mem is $\subseteq$ transitivity. mem_principal is the membership rfl-unfolding.

Factoid 1.7a (one-one + inclusion-reversing). principal_le_iff : $\uparrow X \sqsubseteq \uparrow Y \leftrightarrow Y \subseteq X$ — Scott’s $X \subseteq Y \iff \uparrow Y \sqsubseteq \uparrow X$, the **variance flip** (smaller neighbourhood $\Rightarrow$ larger principal

filter $\Rightarrow$ more information). $\rightarrow$ evaluates $\sqsubseteq$ at the token X (using $X \in \uparrow X$ since $X \subseteq X$) and reads $Y \subseteq X$ off $X \in \uparrow Y$; $\leftarrow$ chains $Y \subseteq X \subseteq Z$. Injectivity `principal_injective` ($\uparrow X = \uparrow Y \Rightarrow X = Y$) feeds both `le_of_eq` directions through `principal_le_iff` into `Set.Subset.antisymm`.

Factoid 1.7b (density of finite elements). `eq_iUnion_principal`: $x.\text{mem } Z \leftrightarrow \exists X, \exists hX : x.\text{mem } X, (\uparrow X).\text{mem } Z$ — Scott’s $x = \bigcup \{\uparrow X \mid X \in x\}$ written as union membership (concrete, avoiding $\bigcup$ over a `Set (Set  $\alpha$ )`). $\rightarrow$ uses $X = Z$ ($Z \in \uparrow Z$); $\leftarrow$ is one application of upward closure `x.up_mem` ($X \subseteq Z$ with $Z \in \mathcal{D}$). All five declarations audit to `[propext, Quot.sound]`.

Factoid 1.7a

- **Mathematical Target:** “*obvious*”: $X \mapsto \uparrow X$ one-one & inclusion-reversing — `principal_le_iff` ($\uparrow X \sqsubseteq \uparrow Y \iff Y \subseteq X$) + `principal_injective`
- **Lean File:** — (see proof notes)

Scott’s *principal filter* $\uparrow X = \{Y \in \mathcal{D} \mid X \subseteq Y\}$ is `principal` ($hX : V.\text{mem } X$) : `V.Element`, with `mem Y := V.mem Y  $\wedge$  X  $\subseteq$  Y`. The four filter laws: `sub` is the first projection; `master_mem` = $\langle V.\text{master_mem}, V.\text{sub_master } hX \rangle$ (this is where the new `sub_master` field earns its keep — $X \subseteq \Delta$); `inter_mem` combines `Set.subset_inter` (from $X \subseteq Y_1, X \subseteq Y_2$) with one use of `V.inter_mem`, taking X itself as the consistency witness $X \subseteq Y_1 \cap Y_2$; `up_mem` is $\subseteq$ transitivity. `mem_principal` is the membership `rfl`-unfolding.

Factoid 1.7a (one-one + inclusion-reversing). `principal_le_iff`: $\uparrow X \sqsubseteq \uparrow Y \leftrightarrow Y \subseteq X$ — Scott’s $X \subseteq Y \iff \uparrow Y \sqsubseteq \uparrow X$, the **variance flip** (smaller neighbourhood $\Rightarrow$ larger principal filter $\Rightarrow$ more information). $\rightarrow$ evaluates $\sqsubseteq$ at the token X (using $X \in \uparrow X$ since $X \subseteq X$) and reads $Y \subseteq X$ off $X \in \uparrow Y$; $\leftarrow$ chains $Y \subseteq X \subseteq Z$. Injectivity `principal_injective` ($\uparrow X = \uparrow Y \Rightarrow X = Y$) feeds both `le_of_eq` directions through `principal_le_iff` into `Set.Subset.antisymm`.

Factoid 1.7b (density of finite elements). `eq_iUnion_principal`: $x.\text{mem } Z \leftrightarrow \exists X, \exists hX : x.\text{mem } X, (\uparrow X).\text{mem } Z$ — Scott’s $x = \bigcup \{\uparrow X \mid X \in x\}$ written as union membership (concrete, avoiding $\bigcup$ over a `Set (Set  $\alpha$ )`). $\rightarrow$ uses $X = Z$ ($Z \in \uparrow Z$); $\leftarrow$ is one application of upward closure `x.up_mem` ($X \subseteq Z$ with $Z \in \mathcal{D}$). All five declarations audit to `[propext, Quot.sound]`.

Factoid 1.7b

- **Mathematical Target:** “*also obvious*”: $x = \bigcup \{\uparrow X \mid X \in x\}$ for every $x \in |\mathcal{D}|$ — `eq_iUnion_principal`
- **Lean File:** — (see proof notes)

Scott’s *principal filter* $\uparrow X = \{Y \in \mathcal{D} \mid X \subseteq Y\}$ is `principal` ($hX : V.\text{mem } X$) : `V.Element`, with `mem Y := V.mem Y  $\wedge$  X  $\subseteq$  Y`. The four filter laws: `sub` is the first projection; `master_mem` = $\langle V.\text{master_mem}, V.\text{sub_master } hX \rangle$ (this is where the new `sub_master` field earns its keep — $X \subseteq \Delta$); `inter_mem` combines `Set.subset_inter` (from $X \subseteq Y_1, X \subseteq Y_2$) with one use of `V.inter_mem`, taking X itself as the consistency witness $X \subseteq Y_1 \cap Y_2$; `up_mem` is $\subseteq$ transitivity. `mem_principal` is the membership `rfl`-unfolding.

Factoid 1.7a (one-one + inclusion-reversing). `principal_le_iff`: $\uparrow X \sqsubseteq \uparrow Y \leftrightarrow Y \subseteq X$ — Scott’s $X \subseteq Y \iff \uparrow Y \sqsubseteq \uparrow X$, the **variance flip** (smaller neighbourhood $\Rightarrow$ larger principal filter $\Rightarrow$ more information). $\rightarrow$ evaluates $\sqsubseteq$ at the token X (using $X \in \uparrow X$ since $X \subseteq X$) and reads $Y \subseteq X$ off $X \in \uparrow Y$; $\leftarrow$ chains $Y \subseteq X \subseteq Z$. Injectivity `principal_injective` ($\uparrow X = \uparrow Y \Rightarrow X = Y$) feeds both `le_of_eq` directions through `principal_le_iff` into `Set.Subset.antisymm`.

Factoid 1.7b (density of finite elements). `eq_iUnion_principal`: $x.\text{mem } Z \leftrightarrow \exists X, \exists hX : x.\text{mem } X, (\uparrow X).\text{mem } Z$ — Scott’s $x = \bigcup \{\uparrow X \mid X \in x\}$ written as union membership (concrete, avoiding $\bigcup$ over a `Set (Set  $\alpha$ )`). $\rightarrow$ uses $X = Z$ ($Z \in \uparrow Z$); $\leftarrow$ is one application

of upward closure $x.\text{up_mem}$ ($X \subseteq Z$ with $Z \in \mathcal{D}$). All five declarations audit to `[propext, Quot.sound]`.

Definition 1.8 (order)

- **Mathematical Target:** approximation $x \sqsubseteq y \iff x \subseteq y$ — `instance : PartialOrder Element` (choice-free `le_antisymm` via `Element.ext`)
- **Lean File:** — (see proof notes)

`Element V` is Scott’s filter (Def 1.6): a membership predicate `mem : Set  $\alpha$   $\rightarrow$  Prop` with `sub` ($x \subseteq \mathcal{D}$), `master_mem` ($\Delta \in x$), `inter_mem` (closed under $\cap$), and `up_mem` (upward closed in $\mathcal{D}$). Mirroring `InfoSys.Element`, the early helper `Element.ext` (membership-equality $\implies$ equality, proved by `rcases` on both structures + `funext/propext`, *not congr*) keeps the `PartialOrder` instance (Def 1.8’s approximation order $x \sqsubseteq y \iff x \subseteq y$) choice-free: `le_antisymm` is just `Element.ext fun X => (h1 X, h2 X)`. Footprint `[propext, Quot.sound]`.

Definition 1.8 ($\perp$, total)

- **Mathematical Target:** `bot := principal master_mem ( $\perp = \{\Delta\} = \uparrow\Delta$ )`, `mem_bot` ($Y \in \perp \iff Y = \Delta$); `IsTotal x :=  $\forall y, x \sqsubseteq y \rightarrow y \sqsubseteq x$` (predicate only, existence = Ex 1.24, out of scope)
- **Lean File:** — (see proof notes)

Factoid 1.8a

- **Mathematical Target:** `bot_le` ($\perp \sqsubseteq x$ for all x) + `instance OrderBot Element`; constructive
- **Lean File:** — (see proof notes)

Scott’s bottom element $\perp = \{\Delta\}$ is simply the principal filter of the master neighbourhood: `bot := principal master_mem`, i.e. $\perp = \uparrow\Delta$. `mem_bot` shows it really is the *singleton* $\{\Delta\}$: $Y \in \perp \leftrightarrow Y = \Delta$. The forward direction is where `sub_master` pays off — $Y \in \uparrow\Delta$ gives $Y \in \mathcal{D}$ and $\Delta \subseteq Y$, while `V.sub_master` supplies the reverse $Y \subseteq \Delta$, so `Set.Subset.antisymm` collapses Y to Δ . This is the *variance* curiosity (Pitfall 4): $\perp = \uparrow\Delta$ is the *largest* principal filter (Δ is the largest neighbourhood) yet the *least* element.

Factoid 1.8a ($\perp$ is least). `bot_le :  $\forall x, \perp \sqsubseteq x$` : a member $Y \in \perp$ is $Y = \Delta$ (`mem_bot`), and $\Delta \in x$ is filter axiom (i) `x.master_mem`. Packaged as `instance : OrderBot V.Element` so the $\perp$ notation resolves to $\{\Delta\}$; the instance stays `[propext, Quot.sound]`.

Definition 1.8 (total elements). `IsTotal x :=  $\forall y, x \sqsubseteq y \rightarrow y \sqsubseteq x$` — maximality under the approximation order, kept as a *predicate*. Per Scott, the *existence* of total (maximal) elements above a given x is the classical frontier (Exercise 1.24, needs Zorn/choice) and is deliberately **not** proved here.

Factoid 1.8b (“Examples 1.2–1.5 revisited”: `finite  $\implies$  principal`). Scott’s prose “any explicitly given filter x is principal ... the minimal $X \in x$ tells us all we need to know” is formalized as `eq_principal_of_isMin`: if x has a $\subseteq$ -minimum member X (one with $X \subseteq Y$ for every $Y \in x$), then $x = \uparrow X$. $\subseteq$ is minimality, $\supseteq$ is one `up_mem`. This is the constructive *core*; the step “finite system $\implies$ such a minimum exists” (take the intersection of the finitely many members, itself in x by closure) is the only classical ingredient and is left implicit, so the stated lemma audits to `[propext, Quot.sound]`. All four new declarations are constructive.

Factoid 1.8b

- **Mathematical Target:** `eq_principal_of_isMin` (filter with $\subseteq$ -minimum member X is $\uparrow X$) — constructive core of “finite $\implies$ principal”; the finiteness $\implies$ min step left implicit

- **Lean File:** — (see proof notes)

Scott’s bottom element $\perp = \{\Delta\}$ is simply the principal filter of the master neighbourhood:
`bot := principal master_mem`, i.e. $\perp = \uparrow\Delta$. `mem_bot` shows it really is the *singleton* $\{\Delta\}$:
 $Y \in \perp \leftrightarrow Y = \Delta$. The forward direction is where `sub_master` pays off — $Y \in \uparrow\Delta$ gives $Y \in \mathcal{D}$ and $\Delta \subseteq Y$, while `V.sub_master` supplies the reverse $Y \subseteq \Delta$, so `Set.Subset.antisymm` collapses Y to Δ . This is the *variance* curiosity (Pitfall 4): $\perp = \uparrow\Delta$ is the *largest* principal filter (Δ is the largest neighbourhood) yet the *least* element.

Factoid 1.8a ($\perp$ is least). `bot_le :  $\forall x, \perp \sqsubseteq x$` : a member $Y \in \perp$ is $Y = \Delta$ (`mem_bot`), and $\Delta \in x$ is filter axiom (i) `x.master_mem`. Packaged as `instance : OrderBot V.Element` so the $\perp$ notation resolves to $\{\Delta\}$; the instance stays [`propext`, `Quot.sound`].

Definition 1.8 (total elements). `IsTotal x :=  $\forall y, x \sqsubseteq y \rightarrow y \sqsubseteq x$` — maximality under the approximation order, kept as a *predicate*. Per Scott, the *existence* of total (maximal) elements above a given x is the classical frontier (Exercise 1.24, needs Zorn/choice) and is deliberately **not** proved here.

Factoid 1.8b (“Examples 1.2–1.5 revisited”: `finite  $\implies$  principal`). Scott’s prose “any explicitly given filter x is principal ... the minimal $X \in x$ tells us all we need to know” is formalized as `eq_principal_of_isMin`: if x has a $\sqsubseteq$ -minimum member X (one with $X \subseteq Y$ for every $Y \in x$), then $x = \uparrow X$. $\sqsubseteq$ is minimality, $\supseteq$ is one `up_mem`. This is the constructive *core*; the step “finite system $\implies$ such a minimum exists” (take the intersection of the finitely many members, itself in x by closure) is the only classical ingredient and is left implicit, so the stated lemma audits to [`propext`, `Quot.sound`]. All four new declarations are constructive.

Example 1.B

- **Mathematical Target:** $B = \{\sigma\Sigma^* \mid \sigma \in \Sigma^*\}$ (binary), generalizing 1.4 — `Str := List Bool`, cone $\sigma = \sigma\Sigma^*$, B via `ofNestedOrDisjoint` from prefix `cone_trichotomy`
- **Lean File:** — (see proof notes)

Exercise 1.B-sys

- **Mathematical Target:** “*should be done as an exercise*”: B is a neighbourhood system — `nestedOrDisjoint` (cones pairwise nested-or-disjoint)
- **Lean File:** — (see proof notes)

Exercise 1.B-elt

- **Mathematical Target:** “*an exercise here*”: $\sigma x \in |B|$ for $x \in |B|$ — `sigmaElt  $\sigma$  x` (witness $\sigma(X_1 \cap X_2)$ is a cone); `sigmaElt  $\sigma$   $\perp = \sigma \perp$  (sigmaElt_bot)`
- **Lean File:** — (see proof notes)

Factoid 1.B-mono

- **Mathematical Target:** $\sigma_0 \perp \subseteq \sigma_1 \perp \iff \sigma_0$ is an initial segment of σ_1 — `sigmaBot_le_iff ( $\sigma_0 \perp \subseteq \sigma_1 \perp \iff \sigma_0 <+ \sigma_1$ )`
- **Lean File:** — (see proof notes)

Factoid 1.B-lim

- **Mathematical Target:** $x = \bigcup_n \sigma_n \perp$ (element = limit of finite approx.) — `mem_iff_exists_sigmaBot` (union-of- $\sigma \perp$ form; chain enumeration left to prose / choice)

- **Lean File:** — (see proof notes)

Definition 1.9

- **Mathematical Target:** $\mathcal{D}_0 \cong \mathcal{D}_1$: order-iso of $|\mathcal{D}_0|$ and $|\mathcal{D}_1|$ — `DomainIso` := $V_0.\text{Element} \simeq_o V_1.\text{Element}$, `Isomorphic/ $\cong^D$` := `Nonempty DomainIso` with `refl/symm/trans`; $\simeq_o \text{reflects} \sqsubseteq (\text{map_rel_iff}) =$ Scott's two-way inclusion-preservation
- **Lean File:** `Scott1980/Neighborhood/Basic.lean`

Theorem 1.10

- **Mathematical Target:** element-token system: $[X] = \{x \mid X \in x\}$ (`bracket`); `tokenSystem` : `NeighborhoodSystem` $|\mathcal{D}|$; $\mathcal{D} \cong^D \text{tokenSystem}$ via `tokenIso/isomorphic_tokenSystem` (mutually-inverse `toToken/ofToken`). Facts: `bracket_master` (1), `bracket_inter_nonempty_iff` (2), `bracket_inter` (3), `principal_mem_bracket` (4); one-one `bracket_injective`, preserving `bracket_subset_iff`
- **Lean File:** `Scott1980/Neighborhood/Theorem110.lean`

Theorem 1.11

- **Mathematical Target:** $|\mathcal{D}|$ closed under countable $\bigcap$ (`iInter`, no proviso) and ascending $\bigcup$ (`iUnion`, `Monotone x`) — each again a filter; `GLB iInter_le/le_iInter`, `LUB le_iUnion/iUnion_le`; `mem_iInter/mem_iUnion`
- **Lean File:** `Scott1980/Neighborhood/Theorem111.lean`

Exercise 1.12

- **Mathematical Target:** $\Delta = \mathbb{N}$, final-segment `tail n = {m | n ≤ m}`; `neighborhoodSystem` (`chain` via `ofNestedOrDisjoint`); finite elts `fin n = ↑(tail n)` (`fin_strictMono`); unique limit/total `top` (`le_top`, `top_isTotal`, `isTotal_iff_top`); `element_eq` (every elt `fin n` or `top`, classical) (`Exercise112.lean`)
- **Lean File:** `Scott1980/Neighborhood/Exercise112.lean`

Exercise 1.13

- **Mathematical Target:** assertions about `B = ExampleB.lean`; this file adds the **limit nodes**: `branch p =  $\bigcup_n (p \upharpoonright n) \perp$` (via `Thm 1.11 iUnion`), `branch_mem_iff`, `branchSeq_le_branch`, and `branch_isTotal` (each infinite path is a total/maximal element) (`Exercise113.lean`)
- **Lean File:** `Scott1980/Neighborhood/ExampleB.lean`

Exercise 1.14

- **Mathematical Target:** $\Delta = \mathbb{N}$, $\mathcal{D}$ = finite non-empty subsets $\cup \{\Delta\}$; `neighborhoodSystem` (`manual inter_mem`, not `nested-or-disjoint`); finite elts `fin h = ↑X`; total elts = singletons `singleton_isTotal` (`↑{n}` maximal) (`Exercise114.lean`)
- **Lean File:** `Scott1980/Neighborhood/Exercise114.lean`

Exercise 1.15

- **Mathematical Target:** two infinite finite-element domains: `flat` ($\{\mathbb{N}\} \cup \{\{n\}\}$, fully classified: `flat_classify`, `flat_atom_maximal`, `flat_no_three_chain`, `flat_no_infinite_chain`, `flat_all_finite`) and `stem` ($\{\mathbb{N}, \{0, 1\}\} \cup \{\{n\}\}$, `stem_three_chain`); `not_isomorphic` (3-chain transports under $\simeq$) (`Exercise115.lean`)
- **Lean File:** `Scott1980/Neighborhood/Exercise115.lean`

Exercise 1.16

- **Mathematical Target:** $\Delta = \mathbb{N}$, $\mathcal{D}$ = cofinite subsets; $|\mathcal{D}| \cong \mathcal{P}(\mathbb{N})$ under $\subseteq$ — `cofiniteSystem`, `ofExcluded/toExcluded`, `cofiniteIso` (excluded-point set), `mem_compl_of_finite` ($\bigcap_{n \in F} \{n\}^c = F^c$); total elt `ofExcluded` $\mathbb{N}$ (`ofExcluded_univ_isTotal`); second $\cap$ -closed `fullSystem` (`Cofinite ns`)
- **Lean File:** `Scott1980/Neighborhood/Exercise116.lean`

Exercise 1.17

- **Mathematical Target:** $\Delta = \mathbb{R}$, $\mathcal{D}$ = rational open intervals $\cup \{\Delta\}$; `ratIntervalSystem` (`inter_mem'` via `loo_inter_loo+max/min`), `filterAt` $t = \{X | t \in X\}$ is a filter, `filterAt_injective` ($\mathbb{R} \hookrightarrow |\mathcal{D}|$); full total-elt classification documented as out-of-scope (`RatInterval ns`)
- **Lean File:** `Scott1980/Neighborhood/Exercise117.lean`

Exercise 1.18

- **Mathematical Target:** consistent $C \subseteq \mathcal{D}$ (`FinitelyConsistent`); pairwise-but-not-jointly `triSys/family` (`family_pairwise_nonempty`, `not_finitelyConsistent`); `leastFilter` $\supseteq C$ (`subset_leastFilter/leastFilter_le`, via `interUpTo_appendSeq`); `sInf` of a non-empty family of filters is a filter (`sInf_le/le_sInf`) (`Exercise118.lean`)
- **Lean File:** `Scott1980/Neighborhood/Exercise118.lean`

Exercise 1.19

- **Mathematical Target:** *positive* nbhd system (ii': $X \cap Y \neq \emptyset \iff X \cap Y \in \mathcal{D}$) — `IsPositive`, `ofPositive` (`positive` $\implies$ `system`, in `Basic.lean`); `positive` `positiveExample`; non-positive `notPositiveSystem` ($\{\Delta, \{0, 1\}, \{1, 2\}\}$, intersection $\{1\} \notin \mathcal{D}$; smaller than Hoare's $\mathbb{N} \times \mathbb{N}$) `not_isPositive` (`Exercise119.lean`)
- **Lean File:** `Scott1980/Neighborhood/Exercise119.lean`

Exercise 1.20

- **Mathematical Target:** $\Delta' = \mathcal{D}$, $\mathcal{D}' = \{\uparrow X\}$ with $\uparrow X = \{Y \in \mathcal{D} \mid Y \subseteq X\}$ (`upSet`, $\neq$ principal); `powerSystem`, `powerSystem_isPositive`; $|\mathcal{D}| \cong |\mathcal{D}'|$ via `toPower/ofPower/powerIso`, `isomorphic_powerSystem`; `tokens` $\leftrightarrow$ finite elements one-one (`toPower_principal`)
- **Lean File:** `Scott1980/Neighborhood/Exercise120.lean`

Exercise 1.21

- **Mathematical Target:** (detail Thm 1.10) $\{[X]\}$ over $|\mathcal{D}|$ is *positive* (`tokenSystem_isPositive`) and *complete* (`IsComplete`, `tokenSystem_complete`: every filter fixed by a unique point of `Token` y ; `tokenSystem_toToken_bijective`); consistency $\{X_i | i < n\} \iff \bigcap_{i < n} [X_i] \neq \emptyset$ (`consistent_iff_iInter_bracket_nonempty`)

- **Lean File:** Scott1980/Neighborhood/Exercise121.lean

Exercise 1.22

- **Mathematical Target:** (for topologists) the $[X]$ topologize $|\mathcal{D}|$; open sets = (i) $\sqsubseteq$ -upper $\wedge$ (ii) basic-nbhd; $\sqsubseteq$ = specialization order — `basicOpen`, `instTopologicalSpaceElement`, `isOpen_basicOpen`, `isOpen_iff_upper_basic`, `le_iff_isOpen_imp`, `specializes_iff_le`
- **Lean File:** — (see proof notes)

Exercise 1.23

- **Mathematical Target:** countable system $(\text{enum}/\text{henum}/\text{hsurj}) + [\text{DecidablePred } V.\text{mem}] \Rightarrow$ greedy sequence Y_n/acc gives a **total** element: `greedyElement`, `greedyElement_isTotal` (choice-free, `Y_prefix_consistent`); every filter is sequence-determined `filters_sequence_determined` (classical) (Exercise123.lean)
- **Lean File:** Scott1980/Neighborhood/Exercise123.lean

Exercise 1.24

- **Mathematical Target:** (set theorists) the union of a non-empty **chain** of filters is a filter — `chainUnion` (`inter_mem` via `IsChain.total`), `le_chainUnion`; **with Zorn** every element extends to a total one `exists_total_ge` (`zorn_le_nonempty_Ici0`, `IsMax = IsTotal`) — **classical** (Exercise124.lean)
- **Lean File:** Scott1980/Neighborhood/Exercise124.lean

Exercise 1.25

- **Mathematical Target:** (set theorists) Δ linearly+well-ordered, $\mathcal{D}$ = non-empty upper sets (`finalSegmentSystem`); $|\mathcal{D}| \cong \{\text{non-empty lower sets}\}$ under $\subseteq$ — `finalSegmentClassify` (`lowerSetOf/ofLowerSet`); top element `topElement` is the unique total element (`topElement_isTotal`, `eq_topElement_of_isTotal`); with no maximum it is *not* finite/principal (`topElement_not_principal_of_noMax`)
- **Lean File:** Scott1980/Neighborhood/Exercise125.lean

Exercise 1.26

- **Mathematical Target:** (algebraists) commutative ring A (`[DecidableEq A]`), Δ = finite $F \subseteq A$, $I(F) = \{G \mid F \subseteq \langle G \rangle\}$ (`IFamily`, `IFamily_inter`); `ringSystem`; $|\mathcal{D}| \cong$ ideals of A under $\subseteq$ — `ringIso` (`idealOf/ofIdeal` mutually inverse)
- **Lean File:** Scott1980/Neighborhood/Exercise126.lean

Exercise 1.27

- **Mathematical Target:** *bounded* $X \subseteq |\mathcal{D}|$ (`Bounded`, `sSup` = `sInf` of `upperBounds`, `le_sSup/sSup_le`); $\{U, W\}$ consistent in $\mathcal{D} \iff \{\uparrow U, \uparrow W\}$ `bounded_consistent_pair_iff_bounded` (choice-free); X bounded $\iff$ every finite subset bounded `bounded_iff_finite_bounded` (uses 1.18)
- **Lean File:** Scott1980/Neighborhood/Exercise127.lean

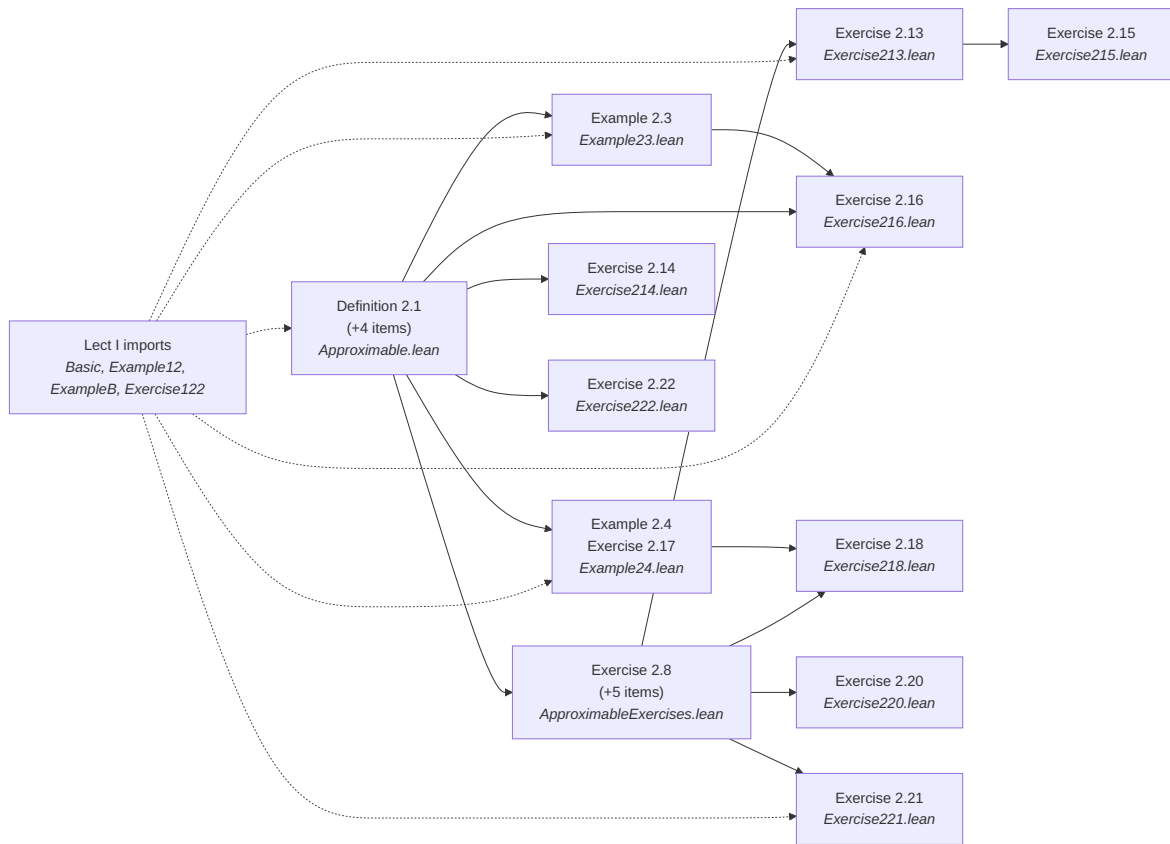

Figure 3: Lean module dependencies for Lecture II: Approximable Mappings.

3.2 Lecture II: Approximable Mappings

Definition 2.1

- **Mathematical Target:** `ApproximableMap`: relation $\text{rel} \subseteq \mathcal{D}_0 \times \mathcal{D}_1$ (`rel_dom/rel_cod`) with (i) `master_rel`, (ii) `inter_right`, (iii) `mono`; relation-extensionality `ext` (`Approximable.lean`)
- **Lean File:** `Scott1980/Neighborhood/Approximable.lean`

Proposition 2.2

- **Mathematical Target:** `toElementMap` ($f(x) = \{Y \mid \exists X \in x, X \text{ f } Y\}$, all of 2.1 used), `mem_toElementMap`, `rel_iff_mem_principal` ($X \text{ f } Y \iff Y \in f(\uparrow X)$), `toElementMap_mono`, `ext_of_toElementMap` (2.2(iv)) (`Approximable.lean`)
- **Lean File:** `Scott1980/Neighborhood/Approximable.lean`

Example 2.3

- **Mathematical Target:** `parityMap` : $B \rightarrow T$: parity of 0's before first 1 via scanner `scan/valElt` (`scan_append stability` $\implies$ `mono`); $T = \text{two-token domain of Ex 1.2}$ (`Example23.lean`)
- **Lean File:** `Scott1980/Neighborhood/Example23.lean`

Example 2.4

- **Mathematical Target:** `runMap` : $B \rightarrow B$: eliminate first run of 1's via state machine `out/del`; `out_mono` (`prefix-monotone`) $\implies$ `mono`; `total` $1\infty \rightarrow \text{partial } \perp$ (`Example24.lean`, `choice-free`)
- **Lean File:** `Scott1980/Neighborhood/Example24.lean`

Theorem 2.5

- **Mathematical Target:** category of nbhd systems + approximable maps: identity `idMap` ($X \text{ I}_D Y \iff X \subseteq Y$), composition `comp g f` ($X \text{ g of } Z \iff \exists Y, X \text{ f } Y \wedge Y \text{ g } Z$), laws `idMap_comp/comp_idMap/comp_assoc` (`Approximable.lean`)
- **Lean File:** `Scott1980/Neighborhood/Approximable.lean`

Proposition 2.6

- **Mathematical Target:** elementwise functor: `toElementMap_idMap` ($\text{I}_D(x) = x$), `toElementMap_comp` ($(\text{g of } f)(x) = \text{g}(f(x))$) — concrete category of sets & functions (`Approximable.lean`)
- **Lean File:** `Scott1980/Neighborhood/Approximable.lean`

Theorem 2.7

- **Mathematical Target:** every domain iso $e: |\mathcal{D}_0| \simeq_o |\mathcal{D}_1|$ comes from an approximable map `ofIso e` (`toElementMap_ofIso`: $(\text{ofIso } e)(x) = e(x)$; `exists_approximable_of_iso`); `finite` $\rightarrow$ `finite` `exists_principal_eq_apply_principal` via directed union `sSupDirected` (`choice-free`)
- **Lean File:** `Scott1980/Neighborhood/Approximable.lean`

Exercise 2.8

- **Mathematical Target:** determined by finite elements `eq_of_toElementMap_principal`; any monotone `fn` on finite elements extends: `ofMono, toElementMap_ofMono_principal` (`ApproximableExercises.lean`)
- **Lean File:** `Scott1980/Neighborhood/ApproximableExercises.lean`

Exercise 2.9

- **Mathematical Target:** approximable `f` satisfies $f(x) = \bigcup \{f(\uparrow X) \mid X \in x\}$ — `toElementMap_mem_iff_principal` (`ApproximableExercises.lean`)
- **Lean File:** `Scott1980/Neighborhood/ApproximableExercises.lean`

Exercise 2.10

- **Mathematical Target:** Prop 2.6 (done in `Approximable.lean`); pointwise `meet` $h(x) = f(x) \cap g(x)$ — `interMap, mem_toElementMap_interMap` (`ApproximableExercises.lean`)
- **Lean File:** `Scott1980/Neighborhood/ApproximableExercises.lean`

Exercise 2.11

- **Mathematical Target:** directed $a : I \rightarrow |D| \implies \bigcup_i a(i)$ is a filter (`iSupDirected, mem/le/le_`); approximable maps preserve directed $\bigcup$ — `toElementMap_iSupDirected`
- **Lean File:** `Scott1980/Neighborhood/ApproximableExercises.lean`

Exercise 2.12

- **Mathematical Target:** directed family $\{f_i\}$ of approximable maps: pointwise union $\bigcup_i f_i$ approximable — `iSupMap, mem_toElementMap_iSupMap` (`ApproximableExercises.lean`)
- **Lean File:** `Scott1980/Neighborhood/ApproximableExercises.lean`

Exercise 2.13

- **Mathematical Target:** (topologists) approximable maps = continuous maps between the $|D|$ spaces of Ex 1.22 — `continuous_toElementMap, ofContinuous, toElementMap_ofContinuous, mem_iff_principal_of_continuous` (choice-free)
- **Lean File:** `Scott1980/Neighborhood/Exercise213.lean`

Exercise 2.14

- **Mathematical Target:** domain iso `e` and nbhd correspondence φ from Thm 2.7; $\text{phi}/\text{phi_spec, rel_ofIso_iff}((\text{ofIso } e).rel \ X \ Y \iff \varphi X \subseteq Y), \text{phi_inter}(\varphi(X \cap X') = \varphi X \cap \varphi X')$ for consistent X, X' (`Exercise214.lean`)
- **Lean File:** `Scott1980/Neighborhood/Exercise214.lean`

Exercise 2.15

- **Mathematical Target:** (topologists) one-token Sierpiński system 0 ; opens of $|D| \leftrightarrow$ approximable maps $D \rightarrow 0$ — `openToMap/mapToOpen/openSet_equiv_map` (builds on 2.13)

- **Lean File:** Scott1980/Neighborhood/Exercise215.lean

The one-token system $\mathbb{O}$ (master $\{*\}$, neighbourhoods $\{\emptyset?, \{*\}\}$) is Scott’s Sierpiński domain: its two elements are $\perp \sqsubset \top$. Building on Ex 2.13, open subsets of $|\mathcal{D}|$ correspond bijectively to approximable maps $\mathcal{D} \rightarrow \mathbb{O}$: `openToMap/mapToOpen` are mutually inverse, packaged as the equivalence `openSet_equiv_map`. The bijection uses choice (`equivSetNat`-style classical packaging of the $\text{open} \leftrightarrow \text{characteristic-map}$ data), so the footprint is `[propext, Classical.choice, Quot.sound]`.

Exercise 2.16

- **Mathematical Target:** $x \mapsto \sigma x$ on $|B|$ is approximable; the parity map $f: B \rightarrow T$ of Ex 2.3 is **uniquely** determined among approximable maps by $f(1x) = \text{true}$, $f(01x) = \text{false}$, $f(00x) = f(x)$
- **Lean File:** Scott1980/Neighborhood/Exercise216.lean
- **Proof Notes:** *First half:* `sigmaMap  $\sigma$  : ApproximableMap B B, toElementMap_sigmaMap ((sigmaMap  $\sigma$ )(x) =  $\sigma x$  = sigmaElt  $\sigma$  x)`. *Second half (uniqueness):* `SatisfiesParityEquations` packages Scott’s three equations; `parityMap_satisfies` confirms `Example23.parityMap` itself meets them via a “shift formula” `Example23.parityMap_toElementMap_sigmaElt` ($f(\sigma x)$ depends on x only through some cone $\text{cone } \tau \in x$, at `valElt(scan( $\sigma++\tau$ ))`); uniqueness (`eq_parityMap_of_satisfies`) pins any equation-satisfying g on every finite element $\sigma \perp$ via `key`, a recursion peeling *two* tokens of σ at a time (mirroring `scan(00 $\tau$ )=scan $\tau$ ) — 1 $\tau$ /01 $\tau$` are immediate from the equations for *any* tail (no recursion), `00 $\tau$` reduces structurally to τ ; the base case $\sigma = []$ and the leftover singleton $\sigma = [\text{false}]$ are the two genuinely order-theoretic steps, resting on flatness of T (`Example23.eq_botElt_of_le`: $\perp$ is the *only* common lower bound of `true, false`). New helper lemmas along the way: `ExampleB.sigmaElt_append/sigmaElt_nil` (σx composes like string concatenation), `Example12.eq_bot_of_le_elemZero_of_le_elemOne` (T ’s flatness at the token level). `#print axioms  $\subseteq$  {propext, Classical.choice, Quot.sound}` (choice from `ApproximableMap.ext`’s `Classical.em`).

Exercise 2.17

- **Mathematical Target:** $g: B \rightarrow B$ of Ex 2.4 is approximable (`runMap`); `runMap` is **uniquely** determined among approximable maps by $g(0x) = 0g(x)$, $g(11x) = g(1x)$, $g(10x) = 0x$, $g(1) = \perp$ — no equation is missing
- **Lean File:** Scott1980/Neighborhood/Example24.lean
- **Proof Notes:** *First half:* `runMap: ApproximableMap B B, relation X g Y  $\leftrightarrow$   $\exists \sigma, X = \sigma \Sigma^* \wedge Y \in B \wedge (\text{out } \sigma) \Sigma$` . *Second half (uniqueness):* `SatisfiesRunEquations` packages Scott’s four equations (the last, $g(1) = \perp$, is a *value* equation at $x = \perp$ only, not quantified over x); `runMap_satisfies` confirms `runMap` itself meets them via two “shift formulas” — `runMap_toElementMap_sigmaElt` (input-side: $g(\sigma x)$ depends on x only through some cone $\text{cone } \tau \in x$, at `out( $\sigma++\tau$ )`) and `sigmaElt_runMap_toElementMap` (output-side: prepending τ_0 to $g(x)$ collapses the same way, since $g(x)$ ’s own membership predicate is already a cone-monotone family); uniqueness (`eq_runMap_of_satisfies`) pins any equation-satisfying g on every finite element $\sigma \perp$ via `key`, a recursion peeling *one* token of σ at a time, mirroring `out`’s own case split: `0 $\tau$` recurses via `hg.zero`; `11 $\tau$` recurses to 1τ via `hg.oneOne` (still one token shorter); `10 $\tau$` and the lone `1` (no tail) are pinned *directly* by `hg.oneZero/hg.one` for any/no tail (no recursion); the base case $\sigma = []$ is the *only* order-theoretic step — $\perp \leq 1\perp$ forces $g(\perp) \leq g(1\perp) = \perp$ by monotonicity, and $\perp$ is already least, so $g(\perp) = \perp$ (no flatness argument needed here, unlike Ex 2.16, since the codomain equation already names

the bottom value directly). New helper lemma: `ExampleB.bot_mem_cone_iff` ($\perp$'s only neighbourhood is the cone of Λ). `#print axioms` $\subseteq$ `{propext, Classical.choice, Quot.sound}` (choice from `ApproximableMap.ext`'s `Classical.em`).

Exercise 2.18

- **Mathematical Target:** “spacing” map $h:B \rightarrow B$ ($b \mapsto b0$) and left inverse k ; `hMap/kMap`, `kMap_comp_hMap` ($k \circ h = I_B$), `kMap_not_injective`, `hMap_not_surjective` (h not an iso) (`Exercise218.lean`, choice-free)
- **Lean File:** `Scott1980/Neighborhood/Exercise218.lean`

Exercise 2.19

- **Mathematical Target:** two-variable approximable maps $f:\mathcal{D}_0 \times \mathcal{D}_1 \rightarrow \mathcal{D}_2$ as ternary relations — `ApproximableMap2`, `toElementMap2`, `rel2_iff_mem_principal`, `toElementMap2_mono` (`ApproximableExercises.lean`)
- **Lean File:** `Scott1980/Neighborhood/ApproximableExercises.lean`

Exercise 2.20

- **Mathematical Target:** powerset domain $\mathcal{P}$ (cofinite nbhds over $\mathbb{N}$); `equivSetNat` ($|\mathcal{P}| \simeq \text{Set } \mathbb{N}$); `unionMap/interMap2` ($\cup, \cap$ via Ex 2.19), `succMap/predMap` ($x \pm 1$)
- **Lean File:** `Scott1980/Neighborhood/Exercise220.lean`

Exercise 2.21

- **Mathematical Target:** system $C \supseteq B$ with finite *and* infinite total sequences (terminator singletons $\{\sigma\}$); `isTotal_singletonElt`, `bot_lt_Lambda` ($\perp \sqsubset \Lambda$); `juxtaposition` `juxtapose` : $C \times C \rightarrow C$ with `juxtapose_cone` (left bias) / `juxtapose_singleton_mem` (`Exercise221.lean`, choice-free)
- **Lean File:** `Scott1980/Neighborhood/Exercise221.lean`

Exercise 2.22

- **Mathematical Target:** (set theorists) any family C closed under non-empty $\bigcap$ + directed $\bigcup$ is inclusion-iso to a domain — closure `C1`, `reprSystem` (nbhds $C(F) = \{G \mid F \subseteq \bar{G}\}$), `reprIso` : $|\text{reprSystem}| \simeq C$ (classical)
- **Lean File:** `Scott1980/Neighborhood/Exercise222.lean`

3.3 Lecture III: Domain Constructs

Definition 3.1

- **Mathematical Target:** `prod`, `prodNbhd` (`Sum.inl '' X` $\cup$ `Sum.inr '' Y`), element pairing `pair`, `Element.fst/snd` (`Product.lean`)
- **Lean File:** `Scott1980/Neighborhood/Product.lean`

Proposition 3.2

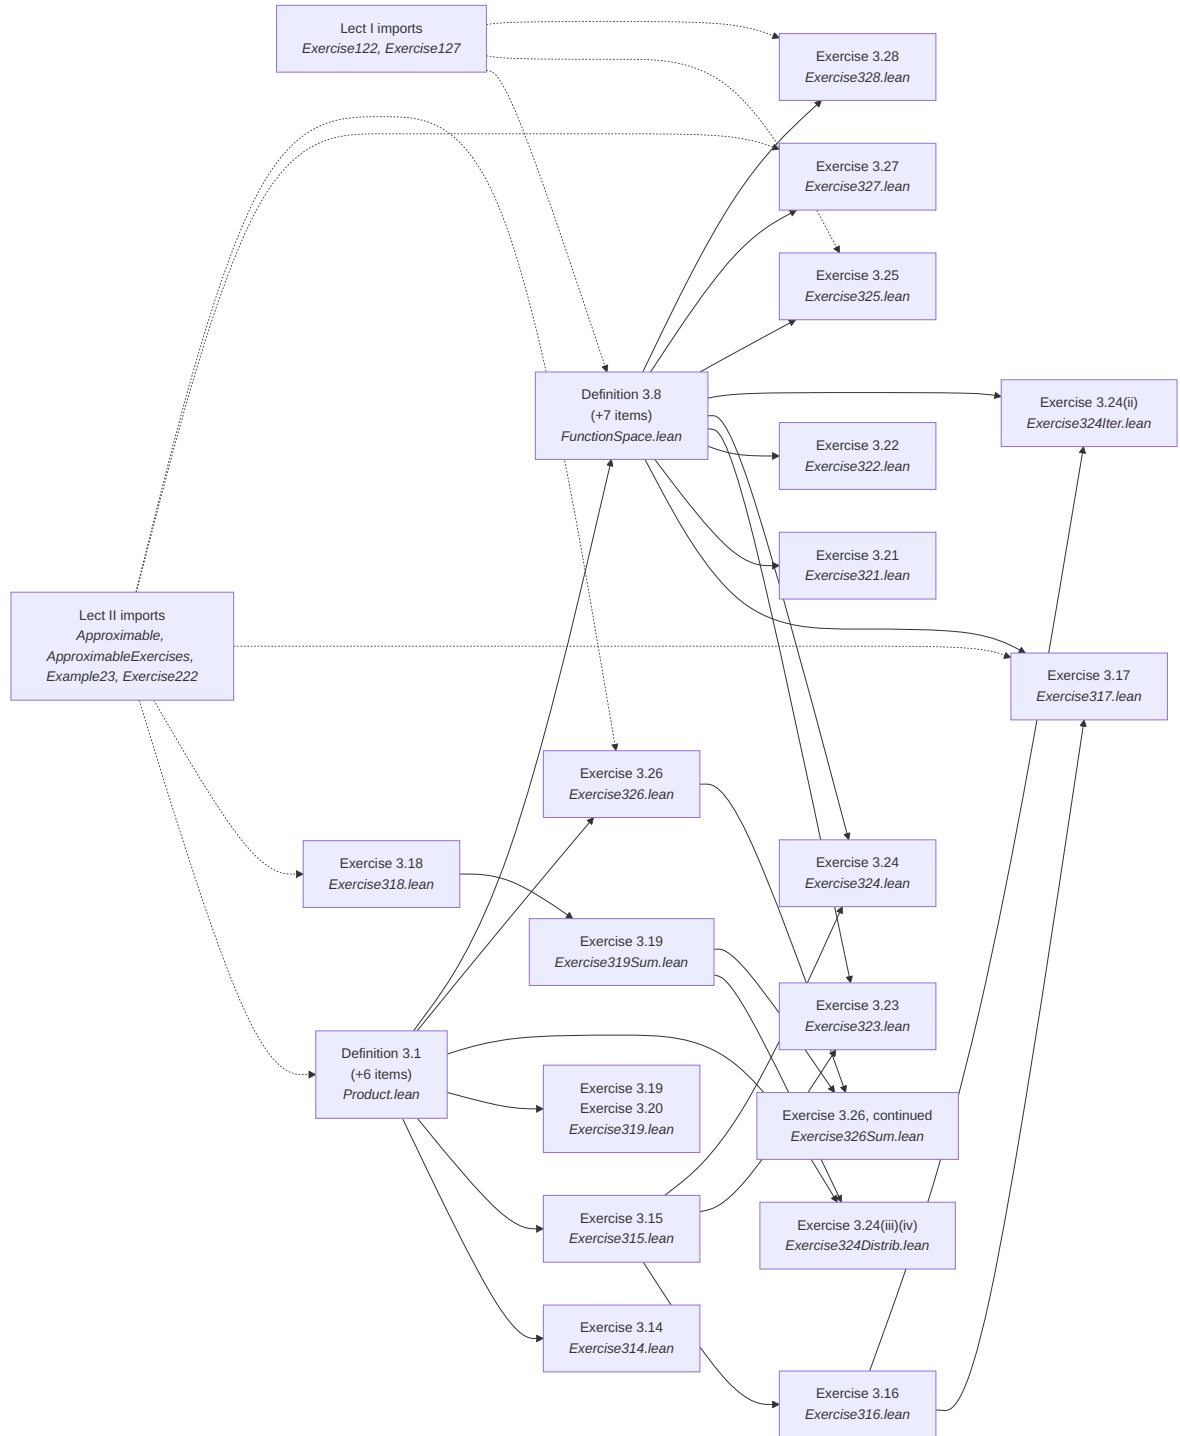

Figure 4: Lean module dependencies for Lecture III: Domain Constructs.

- **Mathematical Target:** prod is a nbhd system; $\text{prodEquiv} : |\mathcal{D}_0 \times \mathcal{D}_1| \simeq_o |\mathcal{D}_0| \times |\mathcal{D}_1|$; pair_le_pair_iff
- **Lean File:** `Scott1980/Neighborhood/Product.lean`

Definition 3.3

- **Mathematical Target:** projections $\text{proj}_0, \text{proj}_1$; paired map paired ; multivariate via prod (`Product.lean`)
- **Lean File:** `Scott1980/Neighborhood/Product.lean`

Proposition 3.4

- **Mathematical Target:** $\text{proj}_0/\text{proj}_1/\text{paired}$ approximable; proj_comp_paired ; $\text{toElementMap_paired_apply} (\langle f, g \rangle (w) = \langle f(w), g(w) \rangle)$ (`Product.lean`)
- **Lean File:** `Scott1980/Neighborhood/Product.lean`

Theorem 3.5

- **Mathematical Target:** $\text{toMap}_2/\text{ofMap}_2/\text{map}_2\text{Equiv}$: $\text{ApproximableMap} (\text{prod } V_0 \ V_1) \ V_2 \simeq \text{ApproximableMap}_2 \ V_0 \ V_1 \ V_2$ (joint $\iff$ separate) (`Product.lean`)
- **Lean File:** `Scott1980/Neighborhood/Product.lean`

Lemma 3.6

- **Mathematical Target:** constant map constMap ; $\text{toElementMap_constMap}$ (`Product.lean`)
- **Lean File:** `Scott1980/Neighborhood/Product.lean`

Proposition 3.7

- **Mathematical Target:** $\text{substitution_toElementMap}$: multivariate functions closed under substitution (`Product.lean`)
- **Lean File:** `Scott1980/Neighborhood/Product.lean`

Definition 3.8

- **Mathematical Target:** $\text{step} ([X, Y] = \{f | X \models f\})$, stepFun , funSpace ; algebra $\text{step_inter_right}/\text{step_subset}/\text{step_master_eq}/\text{step_mem}$ (`FunctionSpace.lean`)
- **Lean File:** `Scott1980/Neighborhood/FunctionSpace.lean`

Proposition 3.9

- **Mathematical Target:** interYs , leastMap (cond. (ii) $X \models_0 Y \iff \bigcap \{Y_i | X \subseteq X_i\} \subseteq Y$), $\text{leastMap_mem_stepFun}$, leastMap_le (minimal element), $\text{stepFun_subset_step_iff}$ (remark after 3.9) (`FunctionSpace.lean`)
- **Lean File:** `Scott1980/Neighborhood/FunctionSpace.lean`

Theorem 3.10

- **Mathematical Target:** $\text{funSpaceEquiv} : |\mathcal{D}_0 \rightarrow \mathcal{D}_1| \simeq \text{ApproximableMap } V_0 \ V_1 \ (\text{toApproxMap}/\text{toF})$
completeness, inclusion-preserving
- **Lean File:** `Scott1980/Neighborhood/FunctionSpace.lean`

Theorem 3.11

- **Mathematical Target:** $\text{eval} : \text{ApproximableMap}_2 \ (\text{funSpace } V_1 \ V_2) \ V_1 \ V_2, \text{evalMap};$
 $\text{evalMap_apply} \ (\text{eval}(f, x) = f(x)) \ (\text{FunctionSpace.lean})$
- **Lean File:** `Scott1980/Neighborhood/FunctionSpace.lean`

Theorem 3.12

- **Mathematical Target:** $\text{curry}, \text{uncurry}; \text{toElementMap_curry_apply}; \text{uncurry_curry}/\text{curry_uncurry}; \text{eval_comp_curry}/\text{curry_eval_comp}; \text{curryEquiv} \ (\text{adjunction}) \ (\text{FunctionSpace.lean})$
- **Lean File:** `Scott1980/Neighborhood/FunctionSpace.lean`

Theorem 3.13(i)

- **Mathematical Target:** $\text{le_iff_toElementMap_le} \ (f \sqsubseteq g \iff \forall x, f(x) \sqsubseteq g(x)) \ (\text{FunctionSpace.lean})$
- **Lean File:** `Scott1980/Neighborhood/FunctionSpace.lean`

Theorem 3.13(ii)

- **Mathematical Target:** $\text{mapsBounded_iff_pointwiseBounded} \ (F \text{ bounded} \iff \{f(x)\} \text{ bounded } \forall x) \ (\text{FunctionSpace.lean})$
- **Lean File:** `Scott1980/Neighborhood/FunctionSpace.lean`

Theorem 3.13(iii)

- **Mathematical Target:** $\text{sSupMaps} + \text{toElementMap_sSupMaps} \ ((\sqcup F)(x) = \sqcup \{f(x)\})$
 $(\text{FunctionSpace.lean})$
- **Lean File:** `Scott1980/Neighborhood/FunctionSpace.lean`

Exercise 3.14

- **Mathematical Target:** tagged product $0\Delta_0 \cup 1\Delta_1$ (disjointness unnecessary); $\text{diag}: D \rightarrow D \times D$;
n-fold products
- **Lean File:** `Scott1980/Neighborhood/Exercise314.lean`

Exercise 3.15

- **Mathematical Target:** product isomorphisms: commutativity, associativity, empty product, functoriality
- **Lean File:** `Scott1980/Neighborhood/Exercise315.lean`

Exercise 3.16

- **Mathematical Target:** $\mathcal{D}_\infty$ over Δ_∞ ; $\mathcal{D}_\infty \cong \mathcal{D} \times \mathcal{D}_\infty$; elements = infinite sequences of $|\mathcal{D}|$ elements

- **Lean File:** Scott1980/Neighborhood/Exercise316.lean

Exercise 3.17

- **Mathematical Target:** $B \rightarrow T\infty$ and $T\infty \rightarrow B$ approximable; section/retraction; iso questions
- **Lean File:** Scott1980/Neighborhood/Exercise317.lean

Exercise 3.18

- **Mathematical Target:** *sum* system $\mathcal{D}_0 + \mathcal{D}_1$; injections in_i , projections out_i ; $\text{out}_i \circ \text{in}_i = \text{I}$; *n*-term sums
- **Lean File:** Scott1980/Neighborhood/Exercise318.lean

Exercise 3.19

- **Mathematical Target:** functorial $f \times g$ and $f + g$ on products/sums; $f \times g = \langle f \circ p_0, g \circ p_1 \rangle$; $\text{out}_i \circ (f + g) \circ \text{in}_i = f/g$
- **Lean File:** Scott1980/Neighborhood/Exercise319.lean

Exercise 3.20

- **Mathematical Target:** (category theorists) $+$ and $\times$ are functors; $\times$ is the categorical product
- **Lean File:** Scott1980/Neighborhood/Exercise319.lean

Exercise 3.21

- **Mathematical Target:** $[Y, Z]$ in $(\mathcal{D}_1 \rightarrow \mathcal{D}_2)$ uniquely determines Y, Z when $Z \neq \Delta_2$; edge case $Z = \Delta_2$
- **Lean File:** Scott1980/Neighborhood/Exercise321.lean

Exercise 3.22

- **Mathematical Target:** composition $\text{comp} : (\mathcal{D}_1 \rightarrow \mathcal{D}_2) \times (\mathcal{D}_0 \rightarrow \mathcal{D}_1) \rightarrow (\mathcal{D}_0 \rightarrow \mathcal{D}_2)$ approximable; $\text{comp}(g, f) = g \circ f$; from *eval* + *curry*
- **Lean File:** Scott1980/Neighborhood/Exercise322.lean

Exercise 3.23

- **Mathematical Target:** (category theorists) domains + approximable maps form a cartesian closed category (3.11, 3.12)
- **Lean File:** Scott1980/Neighborhood/Exercise323.lean

Exercise 3.24

- **Mathematical Target:** more function-space isos: (i) $(\mathcal{D}_0 \rightarrow \mathcal{D}_1 \times \mathcal{D}_2) \cong (\mathcal{D}_0 \rightarrow \mathcal{D}_1) \times (\mathcal{D}_0 \rightarrow \mathcal{D}_2)$, (ii) $(\mathcal{D}_0 \rightarrow \mathcal{D}_1 \infty) \cong (\mathcal{D}_0 \rightarrow \mathcal{D}_1) \infty$; (iii)(iv) as canonical mapping relationships (separated-sum bottom obstructs iso)

- **Lean File:** Scott1980/Neighborhood/Exercise324.lean

Exercise 3.25

- **Mathematical Target:** (topologists) open subsets of $|D|$ form a domain (uses 3.10, Exercises 1.21 & 2.13)
- **Lean File:** Scott1980/Neighborhood/Exercise325.lean

Exercise 3.26

- **Mathematical Target:** conditional $\text{cond}: T \times D \times D \rightarrow D$ ($\text{cond}(\text{true}, x, y) = x$, etc.); sum variant $\text{condSum}: T \times D_0 \times D_1 \rightarrow D_0 + D_1$; $\text{which}: D_0 + D_1 \rightarrow T$ with $\text{cond}(\text{which } x, \text{in}_0 \text{ out}_0 \ x, \text{in}_1 \text{ out}_1 \ x) = x$
- **Lean File:** Scott1980/Neighborhood/Exercise326.lean

Exercise 3.27

- **Mathematical Target:** (set theorists) alt proof $(D_0 \rightarrow D_1)$ is a domain via Ex 2.22; compare with 3.9/3.10
- **Lean File:** Scott1980/Neighborhood/Exercise327.lean

Exercise 3.28

- **Mathematical Target:** minimal element of $\bigcap [X_i, Y_i]$ in function space: $f_0(x) = \bigsqcup \{\uparrow Y_i \mid x \in [X_i]\}$
- **Lean File:** Scott1980/Neighborhood/Exercise328.lean

3.4 Lecture IV: Fixed Points and Recursion

Theorem 4.1

- **Mathematical Target:** every approximable $f: D \rightarrow D$ has a **least** fixed point $\text{fix}(f) = \bigsqcup_n f^n(\perp)$
- **Lean File:** Scott1980/Neighborhood/Theorem41.lean

Theorem 4.2

- **Mathematical Target:** the fixed-point operator $\text{fix}: (D \rightarrow D) \rightarrow D$ is itself approximable; $\text{fix}(f) = \bigsqcup_n f^n(\perp)$
- **Lean File:** Scott1980/Neighborhood/Theorem41.lean

Example 4.3

- **Mathematical Target:** the natural-number domain $\mathbb{N}$ (infinite generalization of Ex 1.2); 0, successor, predecessor
- **Lean File:** Scott1980/Neighborhood/Example43.lean

Example 4.4

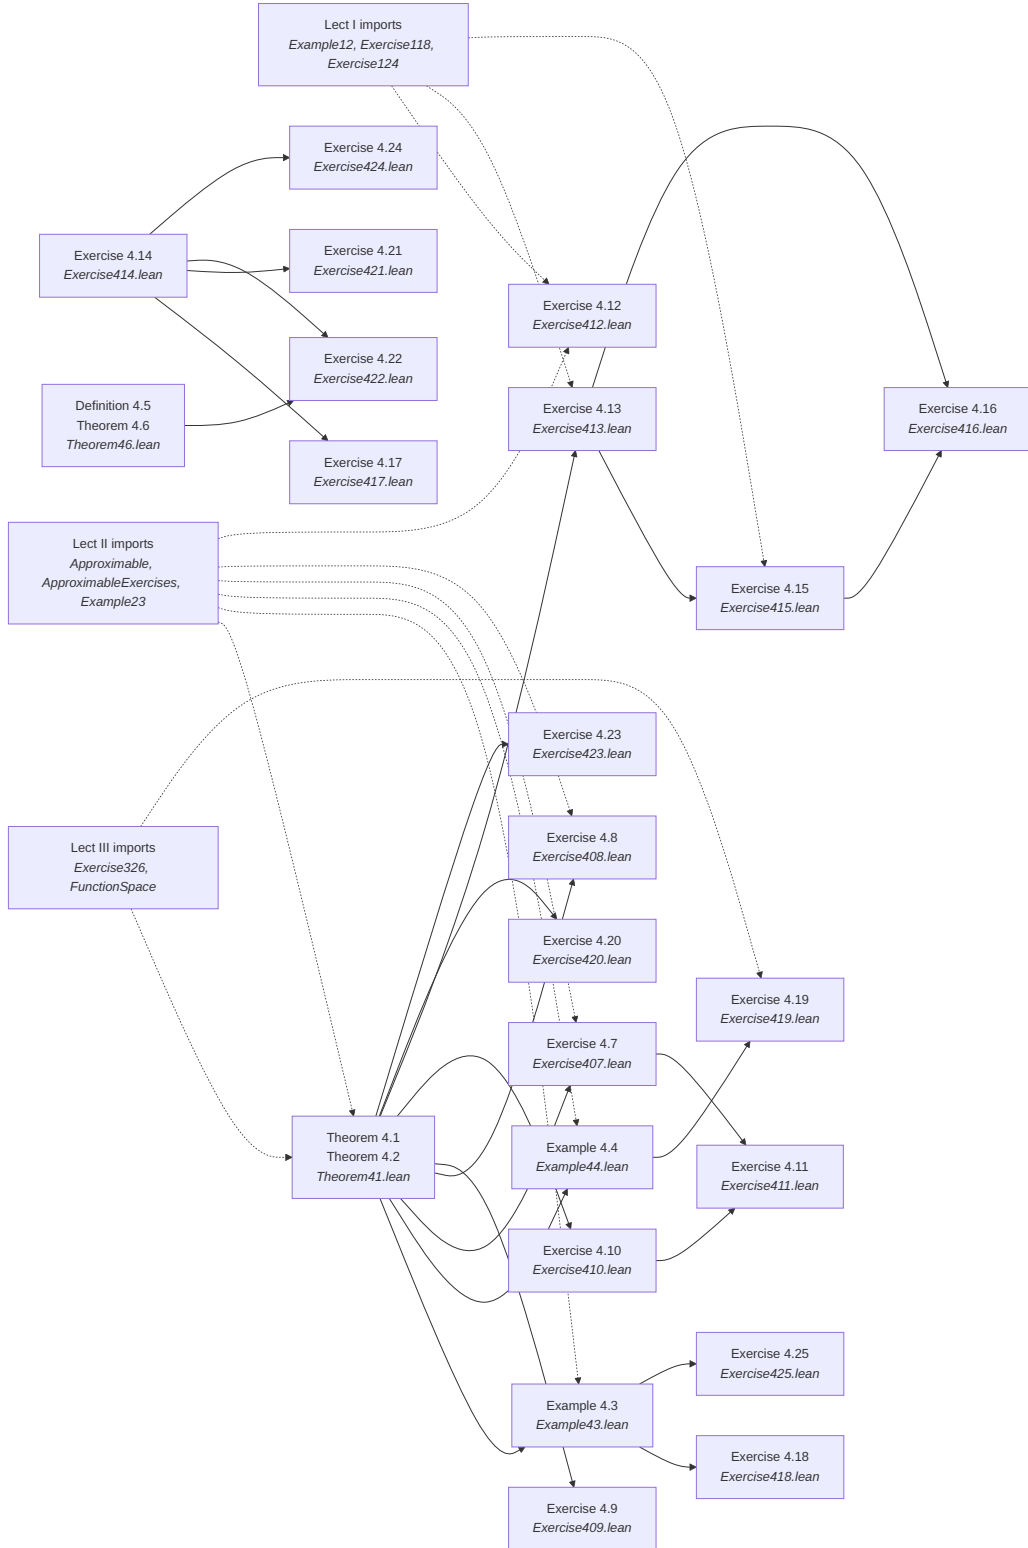

Figure 5: Lean module dependencies for Lecture IV: Fixed Points and Recursion.

- **Mathematical Target:** the domain $\mathcal{C}$ of finite/infinite binary sequences (Ex 2.21) as a structured domain
- **Lean File:** Scott1980/Neighborhood/Example44.lean

Definition 4.5

- **Mathematical Target:** *model for Peano's Axioms* $\langle \mathbb{N}, 0, + \rangle$ (zero not a successor, successor injective, induction)
- **Lean File:** Scott1980/Neighborhood/Theorem46.lean

Theorem 4.6

- **Mathematical Target:** all models of Peano's Axioms are isomorphic
- **Lean File:** Scott1980/Neighborhood/Theorem46.lean

Exercise 4.7

- **Mathematical Target:** $a \sqsubseteq f(a) \implies$ is there a fixed point $x=f(x)$ with $a \sqsubseteq x$?
- **Lean File:** Scott1980/Neighborhood/Exercise407.lean
- **Proof Notes:** Yes — replace $\perp$ by a : the chain $a \sqsubseteq f(a) \sqsubseteq f^2(a) \sqsubseteq \dots$ is increasing hence directed, so $\text{fixAbove } a \ f := \bigsqcup_n f^n(a)$ is a genuine element (approximable maps preserve directed unions, `toElementMap_iSupDirected`), giving a fixed point above a — `fixAbove_isFixed`, `le_fixAbove`, `fixAbove_least`; choice-free)

Exercise 4.8

- **Mathematical Target:** $f:D \rightarrow D$, $S \subseteq |D|$ closure conditions for fixed points — `fix_induction` (fixed-point induction) + the $S=\{x \mid a(x)=b(x)\}$ corollary `fix_induction_eq`
- **Lean File:** Scott1980/Neighborhood/Exercise408.lean

Exercise 4.9

- **Mathematical Target:** an approximable operator (least fixed point over a family)
- **Lean File:** Scott1980/Neighborhood/Exercise409.lean
- **Proof Notes:** the operator $\Psi : ((\mathcal{D} \rightarrow \mathcal{D}) \rightarrow \mathcal{D}) \rightarrow ((\mathcal{D} \rightarrow \mathcal{D}) \rightarrow \mathcal{D})$, built from the cartesian-closed combinators as $\Psi = \text{curry } \Phi$ (`bigPsi`) with `bigPsi_apply :  $\Psi(\theta)(f) = f(\theta(f))$` ; `fix_eq_fixElement_bigPsi :  $\text{fix} = \text{fix}(\Psi)$  via bigPsi_fix+bigPsi_least; operator data choice-free)`

Exercise 4.10

- **Mathematical Target:** construct the relativized domain D_a (elements above a)
- **Lean File:** Scott1980/Neighborhood/Exercise410.lean
- **Proof Notes:** `relSystem a (mem X := a.mem X)` is order-isomorphic to $\{x \in |D| \mid x \sqsubseteq a\}$ via `relIso`; if $f(a)=a$ (e.g. $a=\text{fix}(f)$) then f restricts to $f' : D_a \rightarrow D_a$ (`relMap`), and when $a=\text{fix}(f)$ this f' has a unique fixed point `relMap_unique_fixed`)

Exercise 4.11

- **Mathematical Target:** (Plotkin) fix uniquely determined by general conditions on $D \rightsquigarrow F_D$
- **Lean File:** `Scott1980/Neighborhood/Exercise411.lean`
- **Proof Notes:** fix satisfies uniformity ($\text{fixElement_uniform}$: $h \circ f_0 = f_1 \circ h$, $h(\perp) = \perp \implies h(\text{fix } f_0) = \text{fix } f_1$, by induction + preservation of directed unions); $\text{fix_unique_of_uniform}$ via the inclusion $\text{inclMap} : D_a \hookrightarrow D + \text{Ex 4.10's unique fixed point}$)

Exercise 4.12

- **Mathematical Target:** need f have a *maximum* fixed point? example with many fixed points
- **Lean File:** `Scott1980/Neighborhood/Exercise412.lean`

Exercise 4.13

- **Mathematical Target:** eliminate the apparent circularity between 4.1 and 4.6
- **Lean File:** `Scott1980/Neighborhood/Exercise413.lean`
- **Proof Notes:** $\text{monoFix} = \bigcap \{x \mid f(x) \sqsubseteq x\}$ least fixed point of monotone f (choice-free); (3) `exists\_unique\_nat\_rec` primitive recursion; (4) `nat\_iterate\_unique`)

Exercise 4.14

- **Mathematical Target:** need monotone $f : PA \rightarrow PA$ have a maximum fixed point?
- **Lean File:** `Scott1980/Neighborhood/Exercise414.lean`

Exercise 4.15

- **Mathematical Target:** (set theorists) monotone $f : |D| \rightarrow |D|$ has a *maximal* fixed point (Zorn) — `exists\_maximal\_fixedPoint` via `zorn\_le0` on post-fixed points + `chainUnion`; `exists\_least\_fixedPoint` via `monoFix`; classical
- **Lean File:** `Scott1980/Neighborhood/Exercise415.lean`

Exercise 4.16

- **Mathematical Target:** (fixed-point nuts) the *optimal* fixed point
- **Lean File:** `Scott1980/Neighborhood/Exercise416.lean`
- **Proof Notes:** for non-empty S a set of fixed points of monotone f , $f(\bigcap S) \sqsubseteq \bigcap S$ (f_sInf_le), so $\bigcap S$ carries a least fixed point `optimalFix S`, itself $\sqsubseteq \bigcap S$; `optimalFix` below/consistent with every fixed point in S — `optimalFix\_le`, `optimalFix\_consistent`; choice-free data)

Exercise 4.17

- **Mathematical Target:** (algebraists) semigroup $\langle S, 1, \cdot \rangle$, PS a domain; least x
- **Lean File:** `Scott1980/Neighborhood/Exercise417.lean`

- **Proof Notes:** the least x with $x = \{1\} \cup \{a, b\} \cup x \cdot x$ is the submonoid generated by $\{a, b\}$ — `lfpSet (F a b) = ⟨{a, b}⟩ (lfpSet_eq_closure)`, Knaster–Tarski via Ex 4.14; non-unique — `Set.univ` also fixed (`fixedPoint_not_unique`)

Exercise 4.18

- **Mathematical Target:** verify the assertions about N, F in Example 4.3
- **Lean File:** `Scott1980/Neighborhood/Exercise418.lean`

Exercise 4.19

- **Mathematical Target:** verify Example 4.4; `one : C → T` from the rest by a fixed-point equation
- **Lean File:** `Scott1980/Neighborhood/Exercise419.lean`

Exercise 4.20

- **Mathematical Target:** `fix(f ∘ g) = f(fix(g ∘ f))`
- **Lean File:** `Scott1980/Neighborhood/Exercise420.lean`

Exercise 4.21

- **Mathematical Target:** $\leq \subseteq N \times N$ as a unique fixed-point equation; addition/multiplication
- **Lean File:** `Scott1980/Neighborhood/Exercise421.lean`
- **Proof Notes:** $\leq$ is the unique fixed point of $\ell = \{(n, n)\} \cup \{(n, m^+) \mid (n, m) \in \ell\}$ in $P(N \times N)$ — `leRel_isFixed` + uniqueness `leOp_unique` (induction on the second coordinate); the up-sets `[m] = upSet m` with `upSet_zero/upSet_succ/upSet_unique` (4.13(3)); the addition iso `addIso : N ≃ [m]` (`addIso_apply/_zero/_succ`); multiplication `mulOp_lfp_eq_multiples` (least solution = multiples)

Exercise 4.22

- **Mathematical Target:** N^* satisfying (i)(ii) $\implies$ subset N satisfying (i)(ii)(iii)?
- **Lean File:** `Scott1980/Neighborhood/Exercise422.lean`
- **Proof Notes:** Yes — the least fixed point `nats` of $g(x) = \{0\} \cup x^+$ in $P(N^*)$ (Knaster–Tarski, Ex 4.14) is the smallest subset containing 0 and closed under $^+$, `zero_mem_nats/succ_mem_nats/nats_induction`; `peanoSub : PeanoModel {m // m ∈ nats}` (all three axioms) $\implies$ `exists_peano_submodel`; existence via the axiom of infinity `natPeano`

Exercise 4.23

- **Mathematical Target:** (Eilenberg) unique fixed point under an approximation a_n scheme
- **Lean File:** `Scott1980/Neighborhood/Exercise423.lean`
- **Proof Notes:** given f approximable and a sequence a_n with (i) $a_0 = \perp$, (ii)+(iii) pointwise `IsLUB`, (iv) $a_{n+1} \circ f = a_{n+1} \circ f \circ a_n$; choice-free)

Exercise 4.24

- **Mathematical Target:** (set theorists) Schröder–Bernstein via the fixed-point theorem (Tarski)
- **Lean File:** `Scott1980/Neighborhood/Exercise424.lean`
- **Proof Notes:** for one-one $f:A \rightarrow B$, $g:B \rightarrow A$, a fixed point X of $T(X) = (A - g(B)) \cup g(f(X))$ in $P\ A$ (Knaster–Tarski, Ex 4.14) splits A into $h(a) = f(a)$ on X , $h(a) = g^{-1}(a)$ off X (choice-free), bijection `sbFun` with `sbFun_injective/sbFun_surjective` $\implies$ `schroeder_bernstein + schroeder_bernstein_equiv : A  $\simeq$  B`; classical)

Exercise 4.25

- **Mathematical Target:** the system C_1 over $\{1\}^*$ analogous to N
- **Lean File:** `Scott1980/Neighborhood/Exercise425.lean`
- **Proof Notes:** $C_1 = \{\text{tail } n\} \cup \{\{1^n\}\}$ (nested-or-disjoint over unary strings $1^n \leftrightarrow n$), total elements `oneElem`/partial `oneBot`, successor `consMap` (`consMap_oneElem/_oneBot`), the infinite fixed point `infElt = 1 $\infty$  (infElt_eq)` distinguishing non-flat C_1 from flat N , and the relating map `relateNtoC1 : N  $\rightarrow$  C1`; data choice-free `oneElem/oneBot`, successor `consMap` (`consMap_oneElem/_oneBot`), the infinite fixed point `infElt = 1 $\infty$  (infElt_eq)` distinguishing non-flat C_1 from flat N , and the relating map `relateNtoC1 : N  $\rightarrow$  C1`; data choice-free)

3.5 Lecture V: Typed λ -Calculus

Theorem 5.1

- **Mathematical Target:** every typed λ -term defines an approximable function of its free variables
- **Lean File:** `Scott1980/Neighborhood/Theorem51.lean`

Theorem 5.2

- **Mathematical Target:** the conversion/substitution equation for suitably typed λ -terms
- **Lean File:** `Scott1980/Neighborhood/Theorem52.lean`

Proposition 5.3

- **Mathematical Target:** least fixed point of a pair-valued λ , coordinatewise (Bekić)
- **Lean File:** `Scott1980/Neighborhood/Proposition53.lean`

Proposition 5.4

- **Mathematical Target:** fixed-point equation for $g:(D \rightarrow D)$
- **Lean File:** `Scott1980/Neighborhood/Proposition54.lean`

Table 5.5

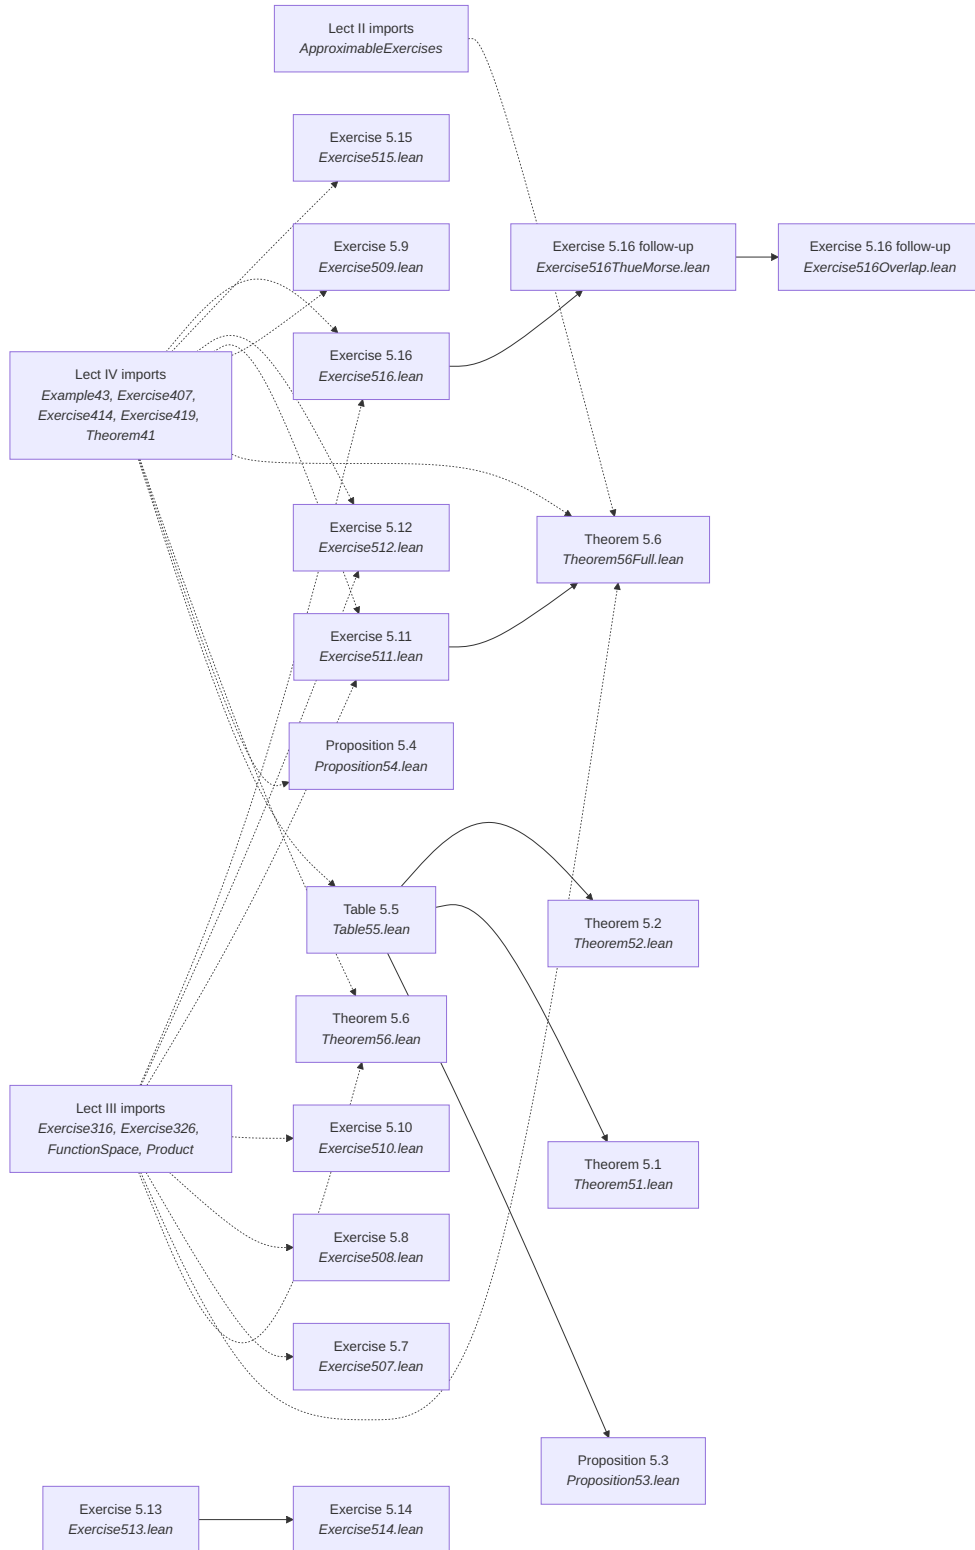

Figure 6: Lean module dependencies for Lecture V: Typed λ -Calculus.

- **Mathematical Target:** summary table: combinators defined via λ -notation
- **Lean File:** Scott1980/Neighborhood/Table55.lean

Theorem 5.6

- **Mathematical Target:** every partial recursive $h:N \rightarrow N$ is λ -definable (over primitives $\text{cond/succ/pred/zero/0}$)
- **Lean File:** Scott1980/Neighborhood/Theorem56.lean
- **Proof Notes:** + Theorem56Full.lean: the full closure `partrec_lamDef` wired against `Mathlib Nat.Primrec' / Nat.Partrec'` on the universal arg domain $\mathcal{N} = N_\infty$, with `rfind` divergence via the directed-sup continuity, and Scott's 1-ary corollary `partrec_one`

Exercise 5.7

- **Mathematical Target:** multi-variable λ /application from one-variable forms (p_0, p_1, pair)
- **Lean File:** Scott1980/Neighborhood/Exercise507.lean

Exercise 5.8

- **Mathematical Target:** (combinator nuts) combinatory completeness: bracket abstraction $(I/K/S)$ eliminates $\lambda, \sigma(\tau)$ only
- **Lean File:** Scott1980/Neighborhood/Exercise508.lean

Exercise 5.9

- **Mathematical Target:** commuting f, g have a least common fixed point (cf. 4.20)
- **Lean File:** Scott1980/Neighborhood/Exercise509.lean

Exercise 5.10

- **Mathematical Target:** the *smash product* $D_0 \otimes D_1$, the *strict function space* $D_0 \rightarrow \perp D_1$, and the adjunction $(D_0 \otimes D_1) \rightarrow \perp D_2 \simeq D_0 \rightarrow \perp (D_1 \rightarrow \perp D_2)$
- **Lean File:** Scott1980/Neighborhood/Exercise510.lean

Exercise 5.11

- **Mathematical Target:** D_∞ as bottomless *stacks*; stack combinators (head/tail/push/-diag/map)
- **Lean File:** Scott1980/Neighborhood/Exercise511.lean

Exercise 5.12

- **Mathematical Target:** the `while` combinator on D by least fixed point
- **Lean File:** Scott1980/Neighborhood/Exercise512.lean

Exercise 5.13

- **Mathematical Target:** a one-one pairing $\text{num}: N \times N \rightarrow N$

- **Lean File:** Scott1980/Neighborhood/Exercise513.lean
- **Proof Notes:** closed form $\text{num}(n,m) = (n+m)(n+m+1)/2+m$ (Cantor diagonal), the three recurrences + `num_injective`, the bijection $\text{numEquiv}:\mathbb{N}\times\mathbb{N}\simeq\mathbb{N}$ (choice-free inverse `unnum`); power-set domains as $(\text{Set } \cdot, \subseteq)$, `setCongr` order-iso $\implies P\ \mathbb{N} \cong P(\mathbb{N}\times\mathbb{N})$, $P\ \mathbb{N} \cong P\ \mathbb{N} \times P\ \mathbb{N}$, $P(\mathbb{N}\times\mathbb{N}) \cong P\ \mathbb{N} \times P\ \mathbb{N}$; choice-free)

Exercise 5.14

- **Mathematical Target:** approximable `fun/graph` mappings
- **Lean File:** Scott1980/Neighborhood/Exercise514.lean
- **Proof Notes:** the tag coding $[n_0, \dots, n_k] = \text{num}(n_0, [n_1, \dots, n_k])$, packaged as `tag>List` $\mathbb{N}\times\mathbb{N}\simeq\mathbb{N}$ (`tag_injective`; `tag_surjective` by strong induction, decreasing via `num_succ_left_gt`). With `Fun` $u\ x = \{m \mid \exists ns \subseteq x, \text{tag } ns\ m \in u\}$, `Graph` $f = \{\text{tag } ns\ m \mid m \in f(\text{entries } ns)\}$ and `IsApprox` (monotone + finite-approx): `Fun_Graph` (`funograph` $= \lambda f.f$ for continuous f), `id_le_Graph_Fun` (`graphofun` $\supseteq \lambda x.x$), `Fun_isApprox` (every `Fun` u is approximable); $Pw = (\text{Set } \mathbb{N}, \subseteq)$ per 4.17/5.13; choice-free)

Exercise 5.15

- **Mathematical Target:** (algebraists) free semigroup $\{0,1\}^*$, $P\{0,1\}^*$ as a domain
- **Lean File:** Scott1980/Neighborhood/Exercise515.lean
- **Proof Notes:** the powerset domain $P\ S = (\text{Set } S, \subseteq)$ of a monoid S , pointwise product $s \cdot t = \{u \cdot v \mid u \in s, v \in t\}$, as a fact about the Kleene algebra $(\text{Set } S, \cup, \cdot, \emptyset, \{1\})$ for any monoid S . `star` $z = \bigcup_n z^n$ (recursive `kpow`, `star_eq`: $z^* = \bigwedge z \cdot z^*$). **Arden's lemma** `arden`: `lfpSet` ($\lambda w.z \cdot w \cup v$) $= z^* \cdot v$ (no `Monotone`). (1) `part1`: `lfpSet` ($\lambda z.\{e\} \cdot z \cup \{e'\}$) $= \text{star}\{e\} \cdot \{e'\}$ with `mem_star_singleton` ($e^* = \{\bigwedge, e, e^2, \dots\}$), specialised to `FreeMonoid Bool` (`part1_freeMonoid`). (2) David Park: `parkX` $= (a \cup b \cdot a^* \cdot b)^* \cdot (c \cup b \cdot a^* \cdot d)$, `parkY` $= a^* \cdot (b \cdot x_0 \cup d)$ — `park_solves` (solve the system) + `park_least` (below every solution = least), by Gaussian elimination via `arden`. Choice-free: reproves `mul_assoc/dist` (`smul_assoc/sunion_mul/smul_union`) at membership level since `Mathlib`'s `Set` $*$ -algebra, $\bigcup$ order lemmas, `Set-power`, `mem_powers_iff` and `Monotone-over-Set` all pull `Classical.choice` here)

Exercise 5.16

- **Mathematical Target:** a fixed-point definition of `neg`: $C \rightarrow C$
- **Lean File:** Scott1980/Neighborhood/Exercise516.lean
- **Proof Notes:** `tail`: $C \rightarrow C$ (`tail` (`bx`) $= x$, `tail` ($\bigwedge$) $= \perp$, the item left to the reader) via `Exercise419.liftC`. `negMap`: $C \rightarrow C$ (`neg` (`0x`) $= 1 \cdot \text{neg}(x)$, `neg` (`1x`) $= 0 \cdot \text{neg}(x)$) solved in closed form (`neg` (σ) $= \text{flip } \sigma$, `flip` $= \text{List.map not}$) via `liftC`; recursion eqs `neg_cons_false/neg_cons_true` (so it is *the* solution) and `negMap_negMap`: `neg` (`neg` x) $= x$ for all $x \in |C|$ — proved by determination on the finite elements (`eq_of_toElementMap_principal`, Ex 2.8) where it is `flipoflip` $= \text{id}$. `dMap`: $C \rightarrow C$ (bit-doubling `d` (`0x`) $= 00 \cdot d(x)$) via `liftC` (`d` (σ) $= \text{double } \sigma$). `mergeMap`: $C \times C \rightarrow C$ (`merge` ($\varepsilon x, \delta y$) $= \varepsilon \cdot \delta \cdot \text{merge}(x, y)$) built directly as an approximable map out of `prod C C` from an explicit interleave value function `mergeVal` on tagged strings (b, σ) (b = total/partial); the boundary Scott flags is resolved by the unique *monotone* convention (`merge` ($\bigwedge, y$) $= \bigwedge$, `merge` ($\varepsilon x, y$) $= \varepsilon \cdot \perp$ once y runs out), proved monotone (`mergeVal_SLe/mergeElem_mono`, the crux of approximability). Recursion eq `mergeMap_cons` (for all x, y , via product extensionality `prodMap_ext`)

and `mergeMap_diag`: `merge(x,x)=d(x)`. All *data* choice-free `[propext,Quot.sound]`; map equalities use `Classical.choice` only via `eq_of_toElementMap_principal`. The **Thue–Morse properties of $t=0 \cdot \text{merge}(\text{neg } t, \text{tail } t)$ are now done too**: `Exercise516ThueMorse` defines `tmOp= $\Phi$` , `tElt=t` (least fixed point), proves the unfolding `tElt_unfold` (`t=0 · merge(neg t, tail t)`); the finite approximants $\Phi^{n+1}(\perp) = (\text{expand}^n[0]) \perp$ are the Thue–Morse-morphism iterates (`expand=0 $\mapsto$ 01, 1 $\mapsto$ 10`), and via the parity bit-function `tm n= $\oplus$ (binary digits of n)` (recurrences `tm(2n)=tm n`, `tm(2n+1)= $\neg$ tm n`) the bridge `expand_iterate_eq` shows `expandn[0]=tmList(2n)`. **Property (a) = `tElt_mem_cone_iff`**: σ is a prefix of t iff $\sigma = \text{tmList } \sigma.\text{length}$ (so the n -th digit of t is `tm n`, Lambek’s digit-sum-mod-2 description) — fully choice-free `[propext,Quot.sound]`. `Exercise516Overlap.lean` proves **property (b)**, overlap-freeness, from scratch (no domain theory): `no_three_consec` (period-1), the descent on the period (even $\rightarrow$ half, odd $\geq 5 \rightarrow$ a run of three), `no_overlap` (no factor of length $2p+1$ with period p), and Scott’s literal cube form `tElt_cube_free` (`t $\neq$ u · a · a · a · v` for nonempty a) via `no_cube`)

3.6 Lecture VI: Domain Equations

Example 6.1

- **Mathematical Target:** iterating $D \times D$ indefinitely into a single domain (D_∞ -style construct)
- **Lean File:** `Scott1980/Neighborhood/Example61.lean`
- **Proof Notes:** $D^\mathbb{S}$, the tree algebra over D , solving $D^\mathbb{S} \cong D + (D^\mathbb{S} \times D^\mathbb{S})$. Tokens live in $\Gamma = \{1,2\}^* 0 \Delta$, modelled as `List Bool  $\times \alpha$` with master $\Gamma = \{t \mid t.2 \in \Delta\}$ (`true=1, false=2`); the three neighbourhood embeddings `embZero X = 0X`, `embL P = 1P`, `embR Q = 2Q`, `embPair P Q = 1P  $\cup$  2Q` with their intersection/subset/injectivity/disjointness API. `MemS D` is the inductive least family containing (i) Γ , (ii) `0X` for $X \in D$, (iii) `1P  $\cup$  2Q` for $P, Q \in D^\mathbb{S}$; `memS_inter` is Scott’s central closure-under-consistent-intersection proof by induction on the derivation (cross cases `0A  $\cap$  (1P  $\cup$  2Q) =  $\emptyset$` discharged via non-emptiness `memS_nonempty`, needing the standing `$\emptyset \notin D$` as `hD`). `Dsharp D hD` packages the system. The **domain equation** `dsharp_domain_equation : Dsharp D hD  $\cong^D$  sum D (prod (Dsharp D hD) (Dsharp D hD))` ... is built as the explicit order-iso `dsharpEquiv` (forward `toS/inverse fromS` filter maps, the inverse laws `fromS_toS/toS_fromS`, and `map_rel_iff'`), routed through the project’s `+` (Ex 3.18) and `$\times$` (Def 3.1) with the shape-inversion lemmas `memS_embZero_inv/memS_embPair_inv/sum_mem_inj0_inv/sum_mem_inj1_inv`. Also the isomorphic injections `inSharp (x $\mathbb{S}$ = $\{\Gamma\} \cup \{0X \mid X \in x\}$, inSharp_le_iff) and pairSharp ($\langle x, y \rangle$ = $\{\Gamma\} \cup \{1P \cup 2Q \mid P \in x, Q \in y\}$, pairSharp_le_iff); $\perp = \{\Gamma\}$ is the system’s own bot. Fully choice-free [propext, Quot.sound] — even the equation iso and order-injection lemmas)`

Example 6.2

- **Mathematical Target:** B, C as solutions of domain equations (isomorphisms)
- **Lean File:** `Scott1980/Neighborhood/Example62.lean`
- **Proof Notes:** $B \cong B+B$ and $C \cong \{\{\Lambda\}\}+C+C$, both presented over `Str = List Bool` with its intersection/subset/injectivity/disjointness API and the neighbourhood-shape classification `memB_cases` (master `$\Sigma^*$ , 0X, 1X); the forward/inverse filter maps toBB/fromBB and the order-iso bbEquiv : |B|  $\simeq_o$  |B + B| against the project’s + (Ex 3.18) give`

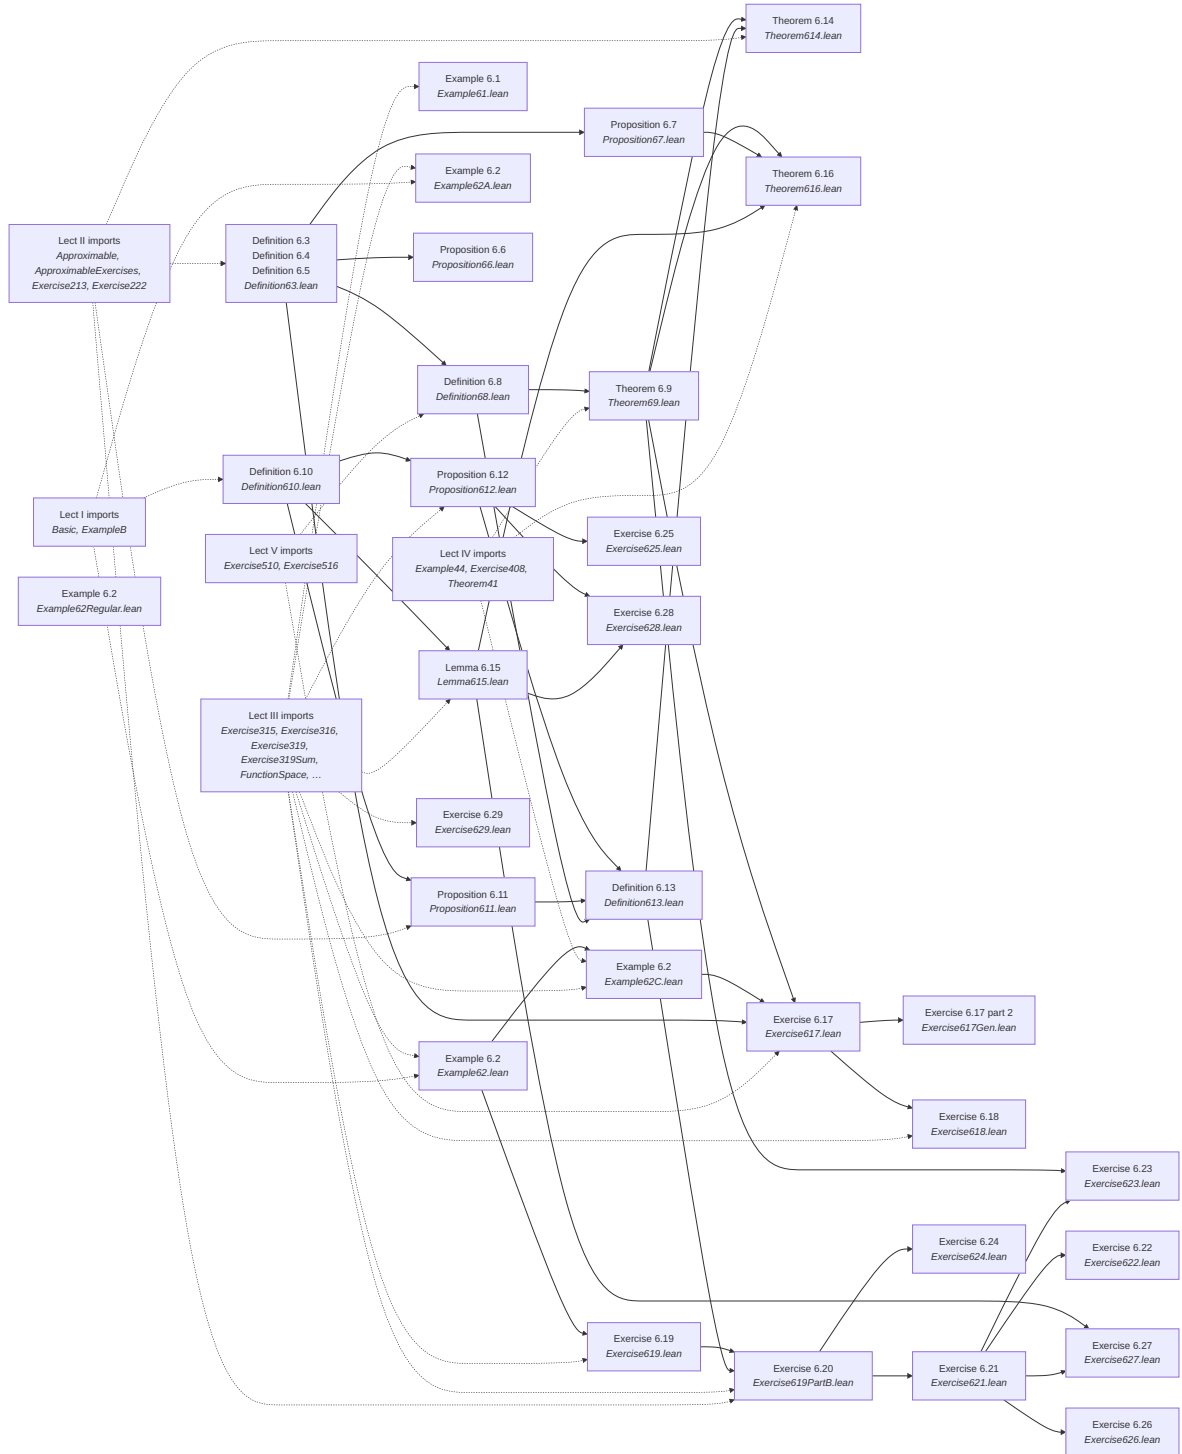

Figure 7: Lean module dependencies for Lecture VI: Domain Equations.

`B_domain_equation : B  $\cong^D$  sum B B ....` `Example62C.lean` first builds the genuine **three-way separated sum** `sum3 V0 V1 V2` over `Option (α ⊕ β ⊕ γ)` (tags `t0/t1/t2`, injections `j0/j1/j2`, `master3`, `full inter_mem`) — nesting the binary sum would add a spurious extra bottom — then the order-iso `ccEquiv : |C|  $\simeq_o$  |K| + C + C|` (`toCC/fromCC`, with `K = unitSys` the `{{Λ}}` summand, the `{Λ} = {[]}` terminator going to the unit copy, `0X/1X` to the two `C` copies) giving `C_domain_equation : C  $\cong^D$  sum3 unitSys C C ....` **Fully choice-free** [`propext`, `Quot.sound`]. The **Aⁿ + Aⁿ generalization** (“a simple, yet interesting generalization of B”) is also done in `Example62A.lean`: the flat `n`-fold product `npow V n` over `Fin n × β` (neighbourhoods the proper products `prodN X =  $\bigcup_j \{j\} \times X_j$` , componentwise `inter_mem`), Scott’s domain `A` over `{0,1}*` as the inductive least family `MemA` with the slot encoding `embTuple i X = i  $\bigcup_{\{j < n\}} 1^j 0 X_j$` (parsed via the uniqueness lemma `slotPre_inj/slot_list_inj`), the system `Asys n hn` (needs `0 < n`), and the order-iso `aaEquiv : |A|  $\simeq_o$  |An + An|` giving `A_domain_equation : Asys n hn  $\cong^D$  sum (npow A n) (npow A n) ...` (choice-free [`propext`, `Quot.sound`]). The closing **eventually-periodic-tree $\leftrightarrow$ regular-event** aside is `Example62Regular.lean`: Scott’s `+/-`-labelled `n`-ary trees `Tree n = List (Fin n) → Bool` with `pos`, the subtree selector `select a σ` (Scott’s `aσ`, recursion `aΛ=a`, `a(iσ)=(ai)σ`), the language `treeLang a = L_a`, and the theorem `eventuallyPeriodic_iff_isRegular : EventuallyPeriodic a  $\leftrightarrow$  (treeLang a).IsRegular` together with `isRegular_iff_exists_eventuallyPeriodic` — exactly the **Myhill–Nerode theorem** (`treeLang_select` identifies `L_{aσ}` with the left quotient `σ-1L_a`, so finitely many subtrees = finitely many left quotients = regular; Prop-level, uses `Classical.choice` via `Mathlib’s Language.isRegular_iff_finite_range_leftQuotient`))

Definition 6.3

- **Mathematical Target:** a *functor* `T` on the category of domains
- **Lean File:** `Scott1980/Neighborhood/Definition63.lean`
- **Proof Notes:** a small, self-contained `Category/Functor` abstraction, generic over an arbitrary category as Scott stresses, the witness instance on `DomainObj/ApproximableMap` (laws = `Thm 2.5`), and `Endofunctor` (the *endofunctor* of `Def 6.3`, with `map_id/map_comp`). **On not using Mathlib’s `CategoryTheory.Category`:** it is structurally identical and *expressive enough* to state all of 6.3–6.7 (it has functors $\Rightarrow$, `Endofunctor.Algebra/Algebra.Hom`, `Limits.IsInitial`, even Lambek’s lemma as `Endofunctor.Algebra.Initial.strInv/left_inv/right_inv`), and a bare `Category DomainObj` instance is itself choice-free [`propext`, `Quot.sound`] — so this is *not* a question of missing vocabulary. It is nonetheless avoided because its *content* is choice-bound: `Endofunctor.Algebra.Initial.left_inv` (the inverse half of Lambek = Scott’s `Prop 6.7`) reports [`propext`, `Classical.choice`, `Quot.sound`] since `Mathlib’s IsInitial` rides on the `Limits` framework, whereas the project’s `lambek/initialIso` (`Props 6.7/6.6`) depend on **no axioms whatsoever**. Adopting `Mathlib` would therefore either inject `Classical.choice` into the flagship `Lecture VI` results (breaking the `#print axioms  $\subseteq$  {propext, Quot.sound}` discipline) or reuse only the bare class and re-prove 6.6–6.7 by hand anyway — paying a heavy transitive import and the $\gg$ (diagrammatic) vs $\odot$ (Scott’s “after”) convention clash for no reusable content. Since Scott asks only for “a small amount of the terminology of category theory”, the ~50-line bespoke class is kept; the full rationale and the empirical axiom comparison live in the module `docstring`.)

Definition 6.4

- **Mathematical Target:** a *T-algebra* `T(E) → E`
- **Lean File:** `Scott1980/Neighborhood/Definition63.lean`

- **Proof Notes:** structure `TAlgebra T` = a carrier object `E` with a structure map `str : T(E) → E`; structure `AlgHom A B` = a morphism `hom : E → F` carrying the commuting-square field `comm : hom ∘ A.str = B.str ∘ T.map hom`. Scott’s remark that the *T-algebras themselves form a category* is discharged by `AlgHom.id` (square closes via `id_comp+map_id+comp_id`) and `AlgHom.comp` (β after α ; the composite square chains `assoc →  $\alpha$ .comm → assoc`), with `@[simp]` projections `id_hom/comp_hom`. Stated over an arbitrary `Category`; $\odot$ reads “g after f” (matching `ApproximableMap.comp`, deliberately *not* the diagrammatic $\gg$). Choice-free `{propext, Quot.sound}`.

Definition 6.5

- **Mathematical Target:** an *initial* T-algebra
- **Lean File:** `Scott1980/Neighborhood/Definition63.lean`
- **Proof Notes:** structure `IsInitial A` bundles the existence datum `desc : (B : TAlgebra T) → AlgHom A B` with the uniqueness field `uniq : ∀ B (h : AlgHom A B), h = desc B` — a *unique* homomorphism into every algebra. The companion structure `Iso X Y` (mutually inverse `hom/inv` with `hom_inv_id/inv_hom_id`) is defined here too, since 6.6/6.7 manufacture isomorphisms. All of it lives over an arbitrary `Category`, exactly as Scott stresses (“could be given for any category”); the concrete `instance : Category DomainObj` (objects = systems, homs = `ApproximableMap`, laws = `Thm 2.5`) witnesses non-vacuity. `IsInitial` itself depends on **no axioms**; module bound `{propext, Quot.sound}` (the `DomainObj` witness).

Proposition 6.6

- **Mathematical Target:** any two initial T-algebras are uniquely isomorphic
- **Lean File:** `Scott1980/Neighborhood/Proposition66.lean`
- **Proof Notes:** the textbook diagram chase. For initial A,B, initiality gives unique homs each way; the helper `comp_desc_eq_id hA hB : (hB.desc A).comp (hA.desc B) = AlgHom.id A` holds because *both* sides are homs $A \rightarrow A$, so `hA.uniq` forces each to equal `hA.desc A.initialIso hA hB : Iso A.carrier B.carrier` then sets `hom = (hA.desc B).hom`, `inv = (hB.desc A).hom`, and reads the two identity laws off `comp_desc_eq_id` in each direction via `congrArg AlgHom.hom`. Uniqueness of the realising hom is `iso_hom_unique := hA.uniq B h`. Verified to **depend on no axioms at all** (not even `propext/Quot.sound`) — purely the category laws; this is precisely *why* the project keeps a bespoke `Category` instead of Mathlib’s choice-bound `Limits.IsInitial`.

Proposition 6.7

- **Mathematical Target:** $i : T(D) \rightarrow D$ initial $\implies T(i)$ initial and i is an isomorphism
- **Lean File:** `Scott1980/Neighborhood/Proposition67.lean`
- **Proof Notes:** formalises the decisive half — the structure map of an initial algebra is an iso. With $A=(D,i)$, the functor builds `tStr A = (T(D), T(i))` and `strHom A : (T(D),T(i)) → (D,i)` (square = `rfl`). Initiality returns the descent hom $j := (hA.desc (tStr A)).hom$; `str_comp_desc` proves $i \odot j = I_D$ (again `(strHom A).comp j` and `id` are both homs $A \rightarrow A$, so `uniq` collapses them). `lambek A hA : Iso (T(D)) D` packages `hom=i, inv=j`: `inv_hom_id` is `str_comp_desc`, and `hom_inv_id (j ∘ i = I_{T(D)})` is the calc $j \odot i = T(i) \odot T(j) = T(i \odot j) = T(I_D) = I_{\{T(D)\}}$ using j ’s square (`comm`), `(map_comp _ _).symm`, `str_comp_desc`, then `map_id`. This is Scott’s point that “to have initial algebras at all we must satisfy $D \cong T(D)$ ”. Verified to **depend on no axioms at all**.

Definition 6.8

- **Mathematical Target:** a functor *continuous on maps*
- **Lean File:** Scott1980/Neighborhood/Definition68.lean
- **Proof Notes:** `ContinuousOnMaps T` — for all domains D, E the induced action $\lambda f. T(f)$ on Scott’s **strict** function space is approximable. Stated *verbatim* over the strict maps: the (co)domain $(D \rightarrow \perp E)$ is the project’s `strictFun D.sys E.sys` (Exercise 5.10), whose elements are exactly the strict approximable maps (`IsStrict f`, i.e. $f(\perp) = \perp$), with the representation `strictFunEquiv : |D → ⊥ E| ≃o StrictMap D E` mirroring Theorem 3.10. “ $\lambda f. T(f)$ is approximable” is rendered (Prop 2.2 / Thm 3.10) as the existence of a representing $\Phi : \text{ApproximableMap } (\text{strictFun } D.\text{sys } E.\text{sys}) (\text{strictFun } (T.\text{obj } D).\text{sys } (T.\text{obj } E).\text{sys})$ whose elementwise action — transported through `toStrictFilter/toStrictMap` — reproduces T on underlying maps: $(\text{toStrictMap } (\Phi.\text{toElementMap } (\text{toStrictFilter } f))) .1 = T.\text{map } f .1$. Since the LHS is the underlying map of a `StrictMap`, the condition automatically forces $T(f)$ strict whenever f is `(ContinuousOnMaps.isStrict_map)`, so a continuous-on-maps T genuinely restricts to Scott’s category of domains and strict maps. Non-vacuity: the identity functor is continuous on maps (`continuousOnMaps_id`, representing $\text{map} = \text{idMap}$ on `strictFun`), built on the generic `idEndofunctor`. **Choice-free** [`propext`, `Quot.sound`]. *Design note:* Scott’s category for 6.8 uses strict maps, but the project’s abstract spine (Defs 6.3–6.7) uses the all-maps `DomainObj` category; this is bridged faithfully by keeping $T : \text{Endofunctor } \text{DomainObj}$ (all maps) while stating the continuity condition over the strict function spaces and *deriving* strictness-preservation, rather than introducing a separate strict-category abstraction.)

Theorem 6.9

- **Mathematical Target:** continuous T with $D \cong T(D) \implies$ a homomorphism $D \rightarrow E$ to any T -algebra
- **Lean File:** Scott1980/Neighborhood/Theorem69.lean
- **Proof Notes:** `nonempty_algHom_of_continuousOnMaps (hT : ContinuousOnMaps T) (iso : Iso (T.obj D) D) (B : TAlgebra T) (hk : IsStrict B.str) : Nonempty (AlgHom ⟨D, iso.hom⟩ B)` — Scott’s existence statement. Lets $i = \text{iso.hom} : T(D) \rightarrow D$, $j = \text{iso.inv} : D \rightarrow T(D)$; j is strict (`isStrict_of_comp_eq_id` from $j \circ i = \text{id}$, any split iso preserves $\perp$), $k = B.\text{str}$ strict by hypothesis (a morphism of Scott’s strict category). A homomorphism h satisfies $h \circ i = k \circ T(h)$, i.e. the fixed-point equation $h = k \circ T(h) \circ j$. The operator $\lambda h. k \circ T(h) \circ j$ on the strict function space $(D \rightarrow \perp E)$ is $\text{Op} = \text{homOp} \circ \Phi$: Φ is Def 6.8’s witness that $\lambda f. T(f)$ is approximable, and homOp (built by Ex 2.8 of `Mono`) is the post/pre-composition $g \mapsto k \circ g \circ j : (T(D) \rightarrow \perp T(E)) \rightarrow (D \rightarrow \perp E)$, with homOpComp the strict composite and action lemma `homOp_apply_filter : homOp(f-hat) = (k ∘ f ∘ j)^^` (proved by reducing — through `strictFunEquiv` injectivity — to single step nbhds $[X, Z]$, the finite factoring being $N := [Y_1, Y_2]$). `Op.fixElement` (Thm 4.1) represents $h := \text{toStrictMap } \dots; \text{toElementMap_fixElement} + \Phi$ ’s defining eq + `homOp_apply_filter` give $h = k \circ T(h) \circ j$, which rearranges via $j \circ i = \text{id}$ (`comp_assoc`, `comp_idMap`) to the `AlgHom` square $h \circ i = k \circ T(h)$. Conclusion is `Nonempty` (a `Prop`), so Φ is extracted from the `Prop`-valued `ContinuousOnMaps` by `Exists.elim` — **fully choice-free** [`propext`, `Quot.sound`]. New reusable helpers: `isStrict_comp`, `isStrict_of_comp_eq_id`, `comp_mono_gen`, `toStrictMap_mono`, `toStrictFilter_mono`, `toStrictFilter_toStrictMap`.)

Definition 6.10

- **Mathematical Target:** the subsystem relation $D \triangleleft E$
- **Lean File:** Scott1980/Neighborhood/Definition610.lean
- **Proof Notes:** structure `Subsystem D E` bundles `sub (D ⊆ E: D.mem X → E.mem X)`, and the essential `inter_closed` (consistency is inherited from $E: D.\text{mem } X \rightarrow D.\text{mem } Y \rightarrow E.\text{mem } (X \cap Y) \rightarrow D.\text{mem } (X \cap Y)$). Elementary API matching Scott’s prose: `Subsystem.refl/Subsystem.` (the `inter_closed` clause threads through `E`) and antisymmetry `Subsystem.antisymm` ($D \triangleleft E$ and $E \triangleleft D \implies D = E$, via the new `NeighborhoodSystem.ext`: `equal mem + equal master  $\implies$  equal system`, other fields `Prop`). **Scott’s remark** `Subsystem.subsystem_iff_subset_of_common`: once $D_0 \triangleleft E$ and $D_1 \triangleleft E$, the subdomain relation collapses to plain inclusion $D_0 \triangleleft D_1 \leftrightarrow D_0 \subseteq D_1$ (the $\leftarrow$ `inter_closed` routes $X \cap Y \in D_1 \subseteq E$ back into D_0 via $D_0 \triangleleft E$). Fully **choice-free** — `refl/subsystem_iff_subset_of_common` depend on *no* axioms, `antisymm/ext` on `[propext, Quot.sound]`.)

Proposition 6.11

- **Mathematical Target:** the subsystems of E form a domain
- **Lean File:** Scott1980/Neighborhood/Proposition611.lean
- **Proof Notes:** `subsystemReprIso : {D // D  $\triangleleft$  E}  $\simeq_o$  |reprSystem (subFam E) ...|` — the set of subsystems $\{D \mid D \triangleleft E\}$, ordered by $\triangleleft$, *forms a domain* (Scott’s one-line corollary of the directed-union remark). Route = the project’s abstract representation theorem **Exercise 2.22** (`reprIso`), exactly as Ex 3.25/3.27. A subsystem $D \triangleleft E$ is determined by its neighbourhood-family $\{X \mid D.\text{mem } X\}$ (via `NeighborhoodSystem.ext` + the standing $D.\text{master} = E.\text{master}$), so the poset is represented by `subFam E = {{X | D.mem X} | D $\triangleleft$ E} $\subseteq \mathcal{P}(\mathcal{P}(\Delta))$ under $\subseteq$; subIso : {D // D $\triangleleft$ E} $\simeq_o$ {S // S $\in$ subFam E} preserves/reflects order by Scott’s remark Subsystem.subsystem_iff_subset_of_common ($\triangleleft = \subseteq$ of neighbourhood-families). The two 2.22 closure hypotheses hold: non-empty intersections subFam_sInter_mem (the intersection subdomain interSys whose nbhds are the common ones) and directed unions subFam_sUnion_mem (the union subdomain unionSys — Scott’s remark; directedness is used precisely to verify closure under consistent intersection). Helper lemmas subFam_master_mem/subFam_mem_E/subFam_inter_closed extract Definition 6.10’s data from subFam membership; ofMem/ofMem_subsystem rebuild a subsystem from a neighbourhood-family. Axioms: the combinatorial core (subFam, interSys/unionSys, the closure lemmas, subIso) is choice-free — subFam/interSys/unionSys depend on no axioms, the rest on [propext, Quot.sound]; subsystemReprIso inherits Classical.choice solely through Exercise 2.22’s reprIso (the documented “for set theorists” exercise), as Ex 3.27 does.)`

Proposition 6.12

- **Mathematical Target:** $D \triangleleft E \implies$ a projection pair i, j
- **Lean File:** Scott1980/Neighborhood/Proposition612.lean
- **Proof Notes:** $i = \text{Subsystem.inj } h : D \rightarrow E$ (element-wise $i(x) = \{Y \in E \mid \exists X \in x, X \subseteq Y\} = \text{toElementMap_inj}$) and $j = \text{Subsystem.proj } h : E \rightarrow D$ ($\text{rel } Y \text{ j } X \leftrightarrow E.\text{mem } Y \wedge D.\text{mem } X \wedge Y \subseteq X$, element-wise $j(y) = y \cap D = \text{toElementMap_proj}$). The `inter_right` law of j is exactly where Definition 6.10’s `inter_closed` is used ($X, X' \in D, Y \subseteq X \cap X' \in E$ via $E.\text{inter_mem} \implies X \cap X' \in D$). The two laws: `Subsystem.proj_comp_inj : j  $\circ$  i = I_D` (both round trips $X \subseteq Y \subseteq Z$ collapse to the identity relation $X \subseteq Z$ on D ; proved with the **choice-free** relational `ApproximableMap.ext`) and `Subsystem.inj_comp_proj_le :`

$\text{ioj} \subseteq \text{I_E}$ (a round trip $Y \subseteq X \subseteq Y'$ through a common D -nbhd is in particular $Y \subseteq Y'$; only an inclusion, not equality). Bundled as `Subsystem.ProjectionPair D E (inj/proj/proj_comp_inj/inj_comp_proj_le)` via `Subsystem.projectionPair`. **Fully choice-free** [`propxt`, `Quot.sound`].)

Definition 6.13

- **Mathematical Target:** a functor *monotone / continuous on domains*
- **Lean File:** `Scott1980/Neighborhood/Definition613.lean`
- **Proof Notes:** `MonotoneOnDomains T :=  $\forall D E, D \triangleleft E \rightarrow T(D) \triangleleft T(E)$` but the pair i, j of 6.12 is mapped to $T(i), T(j)$: `carrier_eq` (the two image carriers $(T.\text{obj}(\alpha, E)).\text{carrier}$, $(T.\text{obj}(\alpha, D)).\text{carrier}$ coincide — needed since the abstract T may change token type, so $T(D) \triangleleft T(E)$ only typechecks once carriers agree), `sub` (the transported $T(D) \triangleleft T(E)$), and `inj_heq/proj_heq` (the canonical 6.12 pair of `sub` is $(T.\text{map } h.\text{inj}, T.\text{map } h.\text{proj})$, up to the carrier transport — hence `HEq`). **Continuous on domains** `ContinuousOnDomains T :=  $\exists \text{hmono} : \text{MonotoneOnDomains } T, \forall \dots$` = preservation of directed unions of subsystems: for any non-empty directed family $\mathcal{F}$ of subsystems of E whose union is the subsystem U , the target-side neighbourhood family `targetFam T hmono (U < E)` (the nbhds of $T(D)$ pushed to $T(E)$'s carrier via `MonotoneAt.carrier_eq`) equals $\bigcup_{D \in \mathcal{F}} \text{targetFam } T \text{ hmono } (D \triangleleft E)$ — exactly the continuity Scott uses in 6.14 ($T(\bigcup_n T^n\{\Gamma\}) = \bigcup_n T(T^{n+1}\{\Gamma\})$). Non-vacuity: `monotoneOnDomains_id/continuousOnDomains_id` (the identity functor; `carrier_eq=rfl`, `targetFam` collapses to the plain family so continuity is just the union hypothesis). **Fully choice-free** [`propxt`, `Quot.sound`].)

Theorem 6.14

- **Mathematical Target:** (main) continuous monotone T with a generating set $\Gamma \implies$ solution $D \cong T(D)$
- **Lean File:** `Scott1980/Neighborhood/Theorem614.lean`
- **Proof Notes:** hypotheses bundled in `Setup` (T continuous on maps + monotone + continuous on domains, generating system Γ with `ceq/hsub` realizing $\{\Gamma\} \triangleleft T(\{\Gamma\})$). The **iterated-functor tower** `iter/Dsys/Dceq/Dchain` builds $T^n(\{\Gamma\})$ over the common token type `Tok` (carrier-type juggling via the choice-free transport lemmas `subsystem_cast/rec_trans/mem_cast/set_rec_trans` and `MonotoneAt.carrier_eq`), with `Dsys_master/chain_le` (the chain $T^n \triangleleft T^m$). The **colimit** `colim =  $\mathcal{D} = \bigcup_n T^n(\{\Gamma\})$` (`inter_mem` via `chain_le`), `Dsys_sub_colim` ($T^n \triangleleft \mathcal{D}$), `Tcolim/colimCeq` ($= T(\mathcal{D})$ over `Tok`), `Dsys_sub_Tcolim` ($T^{n+1} \triangleleft T(\mathcal{D})$), `colim_sub_Tcolim` (easy $\mathcal{D} \subseteq T(\mathcal{D})$) and the **continuity step** `Tcolim_sub_colim` ($T(\mathcal{D}) \subseteq \mathcal{D}$, the only use of `ContinuousOnDomains`, applied to $\mathcal{F} = \text{range}(D\text{sys})$). Hence `Tcolim_eq_colim` : $T(\mathcal{D}) = \mathcal{D}$, the `DomainObj` equality `colimObj_eq`, the identity iso `colimIso` : $\text{Iso } (T(\mathcal{D})) \mathcal{D}$, and the algebra `colimAlg`. **Existence** `nonempty_algHom` (homomorphism into every strict algebra, via **Theorem 6.9**) and the capstone `exists_algebra_with_hom`. The $\rho_n = i_n \circ j_n$ **projection chain** `rho/rho_rel/rho_mono` and `iSupRho_eq_id` ($\bigcup_n \rho_n = I_{\mathcal{D}}$, Scott's uniqueness engine) are also in place. **Uniqueness/initiality** is now complete: `key_rho` : $\rho_{n+1} = \text{colimIso.hom} \odot T(\rho_n) \odot \text{colimIso.inv}$ (Scott's $T(\rho_n) = \rho_{n+1}$) via the `HEq` toolkit `transport_heq/isoOfEq_conj/map_comp_proj_heq` (the crux: `subst` both carrier-eqs, then proof-irrelevance collapses the two `Subsystem` proofs so `eq_of_heq` closes) + `map_rho_heq` ($T.\text{map_comp}$ then `MonotoneAt.inj_heq/proj_heq`). Then $g_n = g \circ \rho_n$ is g -independent: `base_rho_zero_rel/gcomp_rho_zero_indep` (needs $\{\Gamma\}$ **one-point**, $h\Gamma$, giving $\rho_0 = \perp$), `step_gcomp_rho_succ` : $g \circ \rho_{n+1} = k \circ T(g \circ \rho_n) \circ j$ (a $\odot$ -level calc with `Category.assoc` + `g.comm` + `T.map_comp`, using `congrArg` so calc

bridges by defeq). Hence $\text{gcomp_eq } (g = g \circ I = g \circ \bigcup \rho_n = \bigcup (g \circ \rho_n)$ via $\text{iSupRho_eq_id} + \text{comp_idMap}$), algHom_unique , and $\text{exists_unique_strict_algHom}$ (the **initial** T-algebra among strict algebras — required strengthening Thm 6.9’s $\text{nonempty_algHom_of_continuousOnMaps}$ to return a *strict* hom). All **choice-free** [propext, Quot.sound] (incl. the Prop-level uniqueness)

Lemma 6.15

- **Mathematical Target:** projection pair i, j with $j \circ i = I_D$, $i \circ j \sqsubseteq I_E \implies D \trianglelefteq E$ (converse to 6.12)
- **Lean File:** Scott1980/Neighborhood/Lemma615.lean
- **Proof Notes:** $\text{trianglelefteq_of_projectionPair } (i : D \rightarrow E) (j : E \rightarrow D) (hji : j \circ i = I_D) (hij : i \circ j \leq I_E) : D \trianglelefteq E$, the converse of Prop 6.12, for D, E over **possibly different** token types. $D \trianglelefteq E$ (Trianglelefteq , Scott’s $\trianglelefteq$) := $\exists D' \triangleleft E, D \cong^D D'$. Cleaner than Scott’s filter-by-filter argument: isolate the relational predicate $\text{IsGen } i \ j \ X \ Y := X \ i \ Y \wedge Y \ j \ X$ (“Y generates i($\uparrow$ X)”). Three facts drive everything — isGen_exists (every $X \in D$ has a generator: apply $j \circ i = I$ to $X \ i \ D \ X$; uses hji), $\text{isGen_mono}/\text{isGen_mono}'$ (the correspondence is $\subseteq$ -monotone both ways, $Y \subseteq Y' \leftrightarrow X \subseteq X'$; use hji/hij resp.) $\implies$ generators unique in each arg ($\text{isGen_fst_unique}/\text{isGen_snd_unique}$), and isGen_inter (generators closed under $\cap$ when $Y \cap Y' \in E$; just $\text{mono}/\text{inter_right}$). The image system $\text{Dprime } i \ j$ ($\text{mem } Y := \exists X, \text{IsGen } X \ Y, \text{master} := E.\text{master}$) is a nbhd system (isGen_inter gives (ii)) with $\text{Dprime_subsystem} : \text{Dprime } i \ j \triangleleft E$ (its inter_closed clause is isGen_inter). The iso $\text{dprimeEquiv} : D \cong \text{Dprime}$ is $\text{toEl } x = \{Y | \exists X \in x, \text{IsGen } X \ Y\} / \text{ofEl } y = \{X | \exists Y \in y, \text{IsGen } X \ Y\}$, the inverse laws + $\text{map_rel_iff}'$ from generator uniqueness + existence. Also $\text{Subsystem.trianglelefteq} : D \triangleleft E \rightarrow D \trianglelefteq E$ (take $D' = D$), so $D \trianglelefteq E \leftrightarrow \exists$ projection pair $D \rightleftharpoons E$. **Fully choice-free** [propext, Quot.sound] — entirely at the level of Definition 2.1 relations.)

Theorem 6.16

- **Mathematical Target:** initial T-algebra $D \implies D \trianglelefteq E$ for any $E \cong T(E)$
- **Lean File:** Scott1980/Neighborhood/Theorem616.lean
- **Proof Notes:** $\text{trianglelefteq_of_isInitial } (hT : \text{ContinuousOnMaps } T) (\text{Dalg} (\text{hinit} : \text{IsInitial Dalg}) (E) (\text{isoE} : \text{Iso } (T(E)) \ E) : D \trianglelefteq E$. Scott’s argument, reusing Theorem 6.9’s operator $\text{Op} = (\text{homOp } T \ D \ E \ j \ k) \odot \Phi$ on the strict function space $D \rightarrow \perp \ E$. Lambek (Prop 6.7) gives $\text{isoD} : T(D) \cong D$ (so $i = \text{isoD}.\text{hom} = \text{Dalg}.\text{str}$, $j = \text{isoD}.\text{inv}$); $u = \text{isoE}.\text{hom}$, $v = \text{isoE}.\text{inv}$; all four are strict via $\text{isStrict_of_comp_eq_id}$ on the split-iso laws. The Definition-6.8 witnesses Φ for the three hom-spaces $(D, E), (E, D), (E, E)$ are obtained (choice-free, Prop goal). The shared per-step computation is isolated as **opStep**: $\text{toStrictMap}(\text{Op } x).1 = k \odot T(\text{toStrictMap } x).1 \odot j$ (just $\text{homOp_apply_filter} + \Phi$ ’s defining eq $h\Phi$). From it the three approximant chains $H, G, K \ n := \text{toStrictMap}(\text{Op}.\text{iterElem } n).1$ satisfy $H_0 = G_0 = K_0 = \perp$ ($\text{iterElem } 0 = \perp$, botStrict_rel : $\perp$ ’s strict map relates $X \mapsto \text{master}$) and $H_{n+1} = u \odot T(H_n) \odot j$, etc. ($\text{iterElem_succ} + \text{opStep}$). The **ladder** $H_n \odot G_n = K_n$ (induction; step uses **key** : $(u \odot a \odot j) \odot (i \odot b \odot v) = u \odot (a \odot b) \odot v$ via $j \circ i = I$ plus $T.\text{map_comp}$ as $hT.\text{comp}$). $\sqcup$ -decompositions $H_{\text{fix_rel}}/G_{\text{fix_rel}}/K_{\text{fix_rel}}$ ($\text{fixElement_eq_iSupDirected} + \text{mem_iSupDirected}$) give $h \odot g = k$ ($h g k$, diagonalizing the doubly-indexed family at $\max \ m \ n$ via $H_{\text{mono}}/G_{\text{mono}}$). $k \sqsubseteq I_E$ ($h k_{\text{le}}$) because I_E is a fixed point of Op_k ($\text{opStep} + T.\text{map_id} + u \odot v = I$, then $\text{fixElement_le_of_toElementMap_le}$). $g \odot h = I_D$ ($h g h_{\text{id}}$) from **initiality**: h, g are AlgHoms ($h_{\text{comm}}/g_{\text{comm}}$ from $h_{\text{fixeq}}/g_{\text{fixeq}}$ via $\text{toElementMap_fixElement}$), so $g \circ h$ and id both $= \text{hinit}.\text{desc}$. Capstone via Lemma 6.15 trianglelefteq_

of_projectionPair h g hgh_id (h⊙g≤I_E). The whole $\odot$ -vs-.comp friction handled by stating the iso/functor laws (hji,hvu,huv,hmapid,hTcomp) in .comp form (defeq copies). **Fully choice-free** [propext, Quot.sound] incl. the Prop-level initiality use.)

Exercise 6.17

- **Mathematical Target:** algebras for which C is initial
- **Lean File:** Scott1980/Neighborhood/Exercise617.lean
- **Proof Notes:** Pass (both parts) (Exercise617.lean, Exercise617Gen.lean): C is the initial T -algebra for $T(X) = \mathbb{K} + X + X$ (CisInitial : IsInitial Calg). A bespoke $\emptyset$ -free category StrictDomainObj (token type + system + $\emptyset \notin \mathcal{D}$; morphisms = StrictMap) instantiates Category (Def 6.3) — needed because the separated sum sum3 requires $\emptyset \notin \mathcal{D}$, so $T(X) = \mathbb{K} + X + X$ is **not** a total endofunctor of DomainObj and Thm 6.14 can't be invoked directly (cf. Ex 6.19). The **endofunctor** Tc is complete: tcObj (reuses Example 6.2 sum3, $\emptyset$ -free by sum3_nonempty); the three-way sum map sumMap3 = $f_0 + f_1 + f_2$, isStrict_sumMap3, functoriality sumMap3_id/sumMap3_comp $\implies$ Tc : Endofunctor. C is the Tc-algebra Calg = (Cobj, cStr), cStr = ofIso ccEquiv.symm (Example 6.2's iso $C \cong \mathbb{K} + C + C$). **Existence:** descMap : $C \rightarrow E$ via Exercise419.liftC with the head-recursion $\varphi(\Lambda) = e$, $\varphi(b \cdot x) = f_b(\varphi x)$ ($e = k(\text{inj}_0 \top)$, $f_b = k \circ \text{inj}_b$), choice-free. The **AlgHom square** descComm and **uniqueness** descAlgHom_uniq both reduce, via the C -extensionality map_ext_C (Ex 2.8) and the one-step lemma genKey ($k \circ T(g) \circ \text{toCCo}(b \cdot) = f_{\text{bog}}$), to the recursion equations; uniqueness uses rec_determines (any map satisfying the fixed-point recursion equals descMap). **Key infra:** separated-sum element-injections sinj0/1/2, their sumMap3 action sumMap3_sinj_i, monotonicity, and toCCoconsMap b = inj_b / toCC Lambda-hat = inj_0. **The algebras** (answer to part 1): Tc-algebras $k : \mathbb{K} + E + E \rightarrow E =$ a domain E with a distinguished point $e = k(\text{inj}_0)$ and **two strict unary operations** $f_0, f_1 : E \rightarrow E$; C is initial because every finite/infinite binary sequence is the unique f -word over $e/\perp$. **Axioms:** data (descMap, Calg, Tc, sumMap3, sinj_i) is [propext, Quot.sound]; the Prop obligations (descComm, descAlgHom_uniq, CisInitial) inherit Classical.choice **only** from the project's foundational map-extensionality ext_of_toElementMap/eq_of_toElementMap_principal (choice-bound since nbhd-membership isn't decidable) — genuinely unavoidable, consistent with every map-equality result in the repo. **Part 2 (Exercise617Gen.lean, fully formalized):** the binary development is generalized over an **arbitrary alphabet** $A : \text{Type} [\text{DecidableEq } A]$. Strn $A := \text{List } A$, generic cones coneN/memCn, and the domain Cn $A : \text{NeighborhoodSystem} (\text{Strn } A)$ of finite-or-infinite A -sequences; consMapN $a : \text{Cn } A \rightarrow \text{Cn } A$ prepends a . The endofunctor is the **A-indexed separated sum** Tsig(X) = $\mathbb{K} + \sum_{\{a:A\}} X$ (SigTok $A \beta := \text{Option } (\text{Unit} \oplus A \times \beta)$, system sumSig, map sumMapSig, functoriality sumMapSig_id/_comp $\implies$ Tsig : Endofunctor StrictDomainObj), reusing the same bespoke $\emptyset$ -free category. The **iso** $\text{Cn } A \cong \mathbb{K} + \sum_a \text{Cn } A$ (ccEquiv : $(\text{Cn } A). \text{Element} \simeq_o (\text{CCn } A). \text{Element}$, toCC/fromCC, domain equation Cn_domain_equation) gives the algebra Cnalg, and **initiality** CnisInitial : IsInitial Cnalg is proved by the same recursion skeleton (liftCn/map_ext_Cn/genKey/rec_determines), with [Inhabited A] supplying the witnesses (e.g. singleton_nil_ne_univ) that were concrete in the binary case. **Instantiation:** $A := \text{Fin } (n+1)$ recovers Scott's C_n with Cfin_domain_equation : $\text{Cn } (\text{Fin } (n+1)) \cong^D \mathbb{K} + (n+1) \cdot C_n$ and CfinIsInitial; $n=1$ ($\text{Fin } 2 \simeq \text{Bool}$) reproduces the binary case. **The algebras** (part-2 answer): a Tsig-algebra is a domain E with a point e and **A-many strict unary ops** $(f_a)_{\{a:A\}}$; $\text{Cn } A$ is initial because each sequence is the unique f -word over $e/\perp$. **Axioms:** data (Cn, sumSig, sumMapSig, Tsig, ccEquiv, Cnalg, Cn_domain_equation) is [propext, Quot.sound]; the Prop-

level `descAlgHom/CnisInitial/CfinIsInitial` inherit `Classical.choice` only from the foundational map-extensionality, exactly as in part 1.

Exercise 6.18

- **Mathematical Target:** $\mathcal{D}^\infty$ (Ex 3.16) as an initial algebra / domain-equation solution
- **Lean File:** `Scott1980/Neighborhood/Exercise618.lean`
- **Proof Notes:** $\mathcal{D}^\infty$ is the **initial algebra** of the product endofunctor $T(X) = \mathcal{D} \times X$ for a fixed $\emptyset$ -free $\mathcal{D}$; the **domain-equation half** $\mathcal{D}^\infty \cong \mathcal{D} \times \mathcal{D}^\infty$ is Exercise 3.16 (`iter_isomorphic/iterProdIso`). Done in the bespoke `StrictDomainObj` category of Ex 6.17 (where `IsInitial` is Scott’s universal property among strict algebras). **Theorem 6.14 does not apply:** $T(X) = \mathcal{D} \times X$ grows the token set $\mathbb{N} \times \Delta$, so its same-carrier colimit tower is impossible — $\mathcal{D}^\infty$ is built directly à la Ex 3.16. **Element layer:** `prod_nonempty/iterSys_nonempty` ($\emptyset$ -freeness preserved); head/tail reading `iterProdIso_apply` and inverse “cons” `iterProdIso_symm_pair` (via `consSeq`); `iterBot_eq/component_bot/pair_bot`. **Structure maps:** `jmap=ofIso iterProdIso`, `imap=ofIso iterProdIso-1` (algebra map, `isStrict_imap`), `jmap_comp_imap : joi=I`. **Existence:** operator `descOp k f = ko(id×f)oj`, chain `descSeq (h0=⊥, hn+1=descOp k hn)`, and `descMap=iSupMap descSeq (choice-free data, [propxt, Quot.sound])`; `descMap_fix (descMap=descOp descMap, via continuity of k over directed unions — reindex the suprema termwise with kHead)`, `descMap_strict`, and the square `descMap_comm : descMapoi=k○T(descMap)` (`descMap_fix+joi=I`, then `comp_assoc/comp_idMap`). **Uniqueness:** truncation chain $\rho_n = \text{descSeq } \text{imap}$ with closed form $\rho_n(z) = \langle z_0, \dots, z_{n-1}, \perp, \dots \rangle$ (induction, `consSeq`) and `iSupRho_eq_id :  $\bigcup_n \rho_n = I$` (cofinite- Δ structure: each nbhd of z is realized by a finite truncation N from `(iterSys).mem`’s $\exists N$ clause); g-independence `gcomp_rho_zero/gcomp_rho_succ :  $g \circ \rho_{n+1} = \text{Op}_k(g \circ \rho_n)$` (a `comp_assoc/g.comm/prodMap_comp calc`) $\implies$ `comm_unique` (two strict homs agree on every ρ_n via the rel-level `iSupMap` description, hence agree). **Packaging:** `isStrict_prodMap`, `prodObj/prodMapHom/prodFunctor Dom : Endofunctor StrictDomainObj` (`map_id=prodMap_id`, `map_comp=prodMap_comp+idMap_comp`), `iterObj/iterAlg Dom (( $\mathcal{D}^\infty, i$ ))`, `descAlgHom`, and `iterIsInitial Dom : IsInitial (iterAlg Dom)`. **Axioms:** `data (descMap, prodFunctor, iterAlg)` is `[propxt, Quot.sound]`; Prop-level `descMap_comm/comm_unique/iSupRho_eq_id/iterIsInitial` inherit `Classical.choice` only from the foundational directed-suprema membership lemmas — the **same precedent** as Ex 6.17’s `CisInitial`.

Exercise 6.19

- **Mathematical Target:** sum & product on the category of strict maps
- **Lean File:** `Scott1980/Neighborhood/Exercise619.lean`
- **Proof Notes:** **Pass (both parts)** (`Exercise619.lean`, `Exercise619PartB.lean`): Scott’s uniform token-level sum/product over $\Delta \subseteq \{0,1\}^*$ ($\Lambda = []$, $\emptyset \notin \mathcal{D}$) and the answer to “*correct up to isomorphism?*” — yes. `sumTok D0 D1 h0 h1 : mem W := W = { Λ } $\cup$ $\Delta_0 \cup 1\Delta_1 \vee (\exists X \in \mathcal{D}_0, W = 0X) \vee (\exists Y \in \mathcal{D}_1, W = 1Y)$ ($0X = \text{embBit false } X$, $1Y = \text{embBit true } Y$ from Ex 6.2), master insert [] (0 $\Delta_0 \cup 1\Delta_1$), $\emptyset$ -free; capstone sumTok_iso_sum : sumTok D0 D1 h0 h1 $\cong^D$ sum D0 D1 h0 h1 (sumTokEquiv = Example62.bbEquiv generalised from B to arbitrary $\emptyset$ -free $\mathcal{D}_0, \mathcal{D}_1$: toSum/fromSum, @[simp] toSum_mem_inj0/1/fromSum_mem_embF/T, generic sum_mem_inj0_inv/inj1_inv/sum_mem_nonempty, sumTok_mem_embF_inv/embT_inv). prodTok D0 D1 : mem W := $\exists X \in \mathcal{D}_0 \ Y \in \mathcal{D}_1, W = \{\Lambda\} \cup 0X \cup 1Y$ (prodTokNbhd X Y := insert [] (0X $\cup$ 1Y)); mem_prodTokNbhd_nil/false/true $\implies$ Scott (2) prodTokNbhd_`

inter, (1) `prodTokNbhd_subset_iff`, uniqueness `prodTokNbhd_injective`; $\emptyset$ -free; capstone `prodTok_iso_prod : prodTok D0 D1 $\cong^D$ prod D0 D1 via prodTokEquiv.trans (prodEquiv ...).symm where prodTokEquiv : |prodTok| $\simeq_o$ |D0| $\times$ |D1| mirrors Prop 3.2 (fstTok/sndTok, splitting prodTok_mem_split, pairTok, pairTok_fstTok_sndTok/fstTok_pairTok/sndTok_pairTok). All $\subseteq \{\text{propext}, \text{Quot.sound}\}$. Part B (Exercise619PartB.lean): the functor algebra over the fixed token type $\{0,1\}^*$, packaged as a concrete category structure ScottSys ($\emptyset$ -free systems over Str) so $\triangleleft$ needs no carrier transport. Object actions ScottSys.sum/prod; map actions sumMapTok/prodMapTok (full ApproximableMaps, cases via new embBit_not_subset_cross), strictness sumMapTok_isStrict (always)/prodMapTok_isStrict (iff factors), bifunctor laws sum/prodMapTok_id/_comp. Grammar inductive FExpr := const | var | sum | prod, FExpr.obj/FExpr.map. Scott's four properties, all by induction: functors FExpr.map_id/map_comp/map_isStrict; continuous on maps FExpr.map_mono + FExpr.map_continuous (monotone + preserves directed sups = approximable in f , Ex 2.13); monotone on domains FExpr.obj_subsystem (X $\triangleleft$ Y $\implies$ T(X) $\triangleleft$ T(Y)), via sum/prodTok_subsystem; continuous on domains FExpr.obj_continuous (preserves directed unions of subsystems, the Thm 6.14 form). All $\subseteq \{\text{propext}, \text{Quot.sound}\}$.)`

Exercise 6.20

- **Mathematical Target:** the `tok(D)` function on systems
- **Lean File:** `Scott1980/Neighborhood/Exercise619PartB.lean`
- **Proof Notes:** $\lambda\Gamma. \text{tok}(T(\{\Gamma\}))$ is continuous on $\{\Gamma \subseteq \{0,1\}^* \mid \Lambda \in \Gamma\}$, hence a fixed point $\Gamma = \text{tok}(T(\{\Gamma\}))$ exists and $\{\Gamma\} \triangleleft T(\{\Gamma\})$ (so Thm 6.14 applies), for any T from 6.19. Here `tok(D)` = `D.master` (the master *is* Δ) and $\{\Gamma\} = \text{singletonSys } \Gamma$ (one neighbourhood Γ , master Γ , $\emptyset$ -free iff $\Gamma \neq \emptyset$). **Key simplification:** the master of $T(\{\Gamma\})$ is a tiny token recursion `mFun` needing no system data — `const C  $\mapsto$  C.master`, `var  $\mapsto$   $\Gamma$` , and **both** `sum/prod  $\mapsto$  insert  $\Lambda$  (0  $\cdot$  mFun T0  $\Gamma \cup$  1  $\cdot$  mFun T1  $\Gamma$ )` (since `sumTokMaster = prodTokNbhd` on masters); `mFun_eq_master : mFun T  $\Gamma$  = (T.obj { $\Gamma$ }).sys.master`. `mFun T` is `mFun_mono` (monotone) and `mFun_continuous` (in fact fully additive: preserves arbitrary non-empty unions, a fortiori directed — proved via helper `insertTag_continuous`), so it is continuous on the subdomain. **Fixed point** is the explicit Kleene union $\bigcup_n \text{mIter } T \ n$ with `mIter 0 = { $\Lambda$ }`, `mIter (n+1) = mFun T (mIter n)`: `nil_mem_mIter/mIter_mono_step/mIter_mono` (chain $\Lambda \in$, increasing) feed `mFun_iter_fixed : mFun T ( $\bigcup_n \text{mIter } n$ ) =  $\bigcup_n \text{mIter } n$` (continuity applied to `range (mIter T)`). `FExpr.RootedConst` (every constant C has $\Lambda \in C.\text{master}$; free for `sum/prod`) keeps the chain in the domain. Capstones `exists_tok_fixedPoint` ($\exists \Gamma, \Lambda \in \Gamma \wedge \text{mFun } T \ \Gamma = \Gamma$) and `exists_singleton_subsystem :  $\exists \Gamma \ h, (\text{singletonSys } \Gamma \ h).\text{sys} \triangleleft (T.\text{obj } (\text{singletonSys } \Gamma \ h)).\text{sys}$` . All $\subseteq \{\text{propext}, \text{Quot.sound}\}$ (choice-free; needed hand-rolled `insertTag_mono` and `mIter_mono` since Eq. 1e on `Set` and `monotone_nat_of_le_succ` pull `Classical.choice`).

Exercise 6.21

- **Mathematical Target:** functors generated by the operations
- **Lean File:** `Scott1980/Neighborhood/Exercise621.lean`
- **Proof Notes:** extends 6.19B/6.20 with the *coalesced* sum $\oplus$ and *smash* product $\otimes$, and generalizes all of $+$, $\times$, $\oplus$, $\otimes$ to several terms. **Objects:** `oplusTok D0 D1 h0 h1` (= `sumTok` with the improper copies $0\Delta_0, 1\Delta_1$ deleted: `mem W := W = M  $\vee$  ( $\exists X \in D_0, X \neq \Delta_0, W = 0X$ )  $\vee$  ( $\exists Y \in D_1, Y \neq \Delta_1, W = 1Y$ )`, same master $M = \{\Lambda\} \cup 0\Delta_0 \cup 1\Delta_1$) and `otimesTok D0 D1 (mem W := W = M  $\vee$  ( $\exists X \in D_0 \ Y \in D_1, X \neq \Delta_0, Y \neq \Delta_1, W = \text{prodTokNbhd } X \ Y$ ))`; both $\emptyset$ -free (`oplusTok_`

nonempty/otimesTok_nonempty), repackaged as `ScottSys.oplus/ScottSys.otimes`. Coalescence = the two bottoms are **identified** ($\oplus$ =coalesced sum, $\otimes$ =smash), vs $+$, $\times$ which keep them apart. Closure uses `inter_ne_of_ne_left/right` ($X \subseteq \Delta$, $X \neq \Delta \implies X \cap X' \neq \Delta$). **Monotone on domains:** `oplusTok_subsystem/otimesTok_subsystem` carry $\triangleleft$ componentwise (inversions `oplusTok_mem_embF/T_inv`, `otimesTok_mem_prod_inv`). **Maps:** `oplusMapTok/otimesMapTok` are full ApproximableMaps; their relation adds a **master/-collapse row** (every W relates to the top M) that absorbs a boundary hit $f_0(X)=\Delta_0$ collapsing back to the shared bottom, plus $\neq \Delta$ side-conditions on the proper rows. Both **always strict** (`oplus/otimesMapTok_isStrict`); identities `oplus/otimesMapTok_id`; **composition laws** `oplus/otimesMapTok_comp` **require** g_0, g_1 **strict** — strictness of the outer map is exactly what prevents an intermediate top from being re-expanded, the categorical reason $\oplus, \otimes$ are functors only on Scott’s **strict-map** category; monotone `oplus/otimesMapTok_mono`. **Extended algebra** inductive `GExpr := const | var | sum | prod | oplus | otimes` with `GExpr.obj/GExpr.map`, and the four properties by induction over all six constructors: **functors** `GExpr.map_id/map_comp` (`map_comp` carries `IsStrict g`, threaded through subexprs)/`map_isStrict`; **continuous on maps** `GExpr.map_mono+map_continuous`; **monotone on domains** `GExpr.obj_subsystem`; **continuous on domains** `GExpr.obj_continuous`. **6.20 for the extended algebra:** `gFun` (token-master recursion — all four binary ops share the body `insert  $\Lambda$  (0·gFun a  $\cup$  1·gFun b)` since `sumTokMaster=prodTokNbhd` on masters), `gFun_eq_master`, `gFun_mono/gFun_continuous` (reusing Part B’s generic `insertTag_mono/insertTag_continuous`, `singletonSys`), Kleene `gIter/gFun_iter_fixed`, and capstones `gExists_tok_fixedPoint`, `gExists_singleton_subsystem` : $\exists \Gamma h, (\text{singletonSys } \Gamma h).\text{sys} \triangleleft (T.\text{obj} (\text{singletonSys } \Gamma h)).\text{sys}$ (Thm 6.14 applies). **Several terms:** since `GExpr` is closed under the binary ops, every finite combination $T_0 \star T_1 \star \dots \star T_n$ is itself a `GExpr` and inherits all results; `GExpr.naryOp/narySum/naryProd/naryOplus/naryOtimes` package the n -ary right-nested folds, `naryOp_rootedConst` preserves the $\Lambda \in \text{tok}$ side-condition, and `narySum/naryProd/naryOplus/naryOtimes` give each n -ary construct a solution $\Gamma = \text{tok}(T(\{\Gamma\}))$. All $\subseteq \{\text{propext}, \text{Quot.sound}\}$ (choice-free).

Exercise 6.22

- **Mathematical Target:** comment on given domain equations
- **Lean File:** `Scott1980/Neighborhood/Exercise622.lean`
- **Proof Notes:** the “comment on” exercise, formalized as recognising each of the three equations as an instance of the 6.21/6.20 fixed-point machinery, so each has a solution ($\Gamma = \text{tok}(T(\{\Gamma\}))$, $\{\Gamma\} \triangleleft T(\{\Gamma\})$, Thm 6.14 applies). **Constants:** `Cnat =  $\{\{0\}, \{0, \Lambda\}\}$` — the two-point chain $\{0\} \sqsubset \Delta$ ($0 = [\text{false}]$, $\Lambda = []$), built directly with nested-pair `inter_mem` via `inter_eq_self_of_subset_left/right`, $\emptyset$ -free $+$ rooted (`nil_mem_Cnat`); `Cone = singletonSys  $\{\Lambda\}$` = the one-point $\not\models$ (`nil_mem_Cone`). **Equations:** `NExpr =  $\oplus(\text{const Cnat}, \text{var})$` ($N \cong \{\{0\}, \{0, \Lambda\}\} \oplus N$, the **vertical naturals** — coalesced $\oplus$ collapses the per-step choice into a chain), `MExpr =  $+(\text{const Cone}, \text{var})$` ($M \cong \{\{\Lambda\}\} + M$, the **lazy naturals** — separated $+$ keeps stop/continue branching), `NStarExpr N =  $\oplus(\text{const } N, \otimes(\text{const } N, \text{var}))$` ($N^* \cong N \oplus (N \otimes N^*)$, **strict streams over N:** cons-cell functor with smash $\otimes$). **Theorems:** `N_eq_solution/M_eq_solution/NStar_eq_solution N` ($hN: \Lambda \in \text{tok } N$) each `gExists_singleton_subsystem _ rooted`; `NStar_over_N_exists` chains eq-1’s solution (a rooted domain, $\Lambda \in \Gamma_1$) as the datum domain of eq-3 via `gExists_tok_fixedPoint`. Axiom audit $\subseteq \{\text{propext}, \text{Quot.sound}\}$.

Exercise 6.23

- **Mathematical Target:** the initial solution to a domain equation
- **Lean File:** Scott1980/Neighborhood/Exercise623.lean
- **Proof Notes:** **Pass** — all 4 phases (Exercise623.lean, namespace Domain.Neighborhood.Exercise623). the *concrete solution domain* Exp for $\text{Exp} \cong \mathbb{N} \oplus ((\text{Exp} \times \text{Exp}) + (\text{Exp} \times \text{Exp}))$. Functor $\text{Texp } \mathbb{N} = \oplus(\text{const } \mathbb{N}, +(\times(\text{var}, \text{var}), \times(\text{var}, \text{var})))$ as a GExpr (Ex 6.21). Built a **generic ScottSys colimit fixed point for any rooted GExpr T** (the concrete, carrier-fixed analogue of Theorem 6.14, so no HEq transport): $\text{gFix } T = \bigcup_n \text{gIter}^n(\{\Lambda\})$ (the 6.20/6.21 token fixed point, as explicit data — choice-free), $\text{gGen } T = \{\Gamma\}$, $\text{gBase} : \{\Gamma\} \triangleleft T(\{\Gamma\})$, the tower $\text{gTower } T \ n = T^n(\{\Gamma\})$ with $\text{gChain}/\text{gTower_le}/\text{gTower_master}$, the colimit $\text{gColim } T \ hT = \bigcup_n T^n(\{\Gamma\})$ ($\emptyset$ -free system over Str), $\text{gTower_sub_colim} : T^n(\{\Gamma\}) \triangleleft \mathcal{D}$, and the **structure equality** $\text{gColim_obj_eq} : T(\mathcal{D}) = \mathcal{D}$ (via $\text{GExpr.obj_continuous}$ for membership + obj_subsystem for the master; uses ScottSys.ext). Instantiated: $\text{Exp } \mathbb{N} \ h\mathbb{N} := \text{gColim } (\text{Texp } \mathbb{N}) \ _$ and $\text{Exp_structure_eq} : \text{Texp}(\text{Exp}) = \text{Exp}$ (the domain-equation iso, structure map = identity). **Phase 2 DONE:** the strict-map Category ScottSys (objects = $\emptyset$ -free systems over Str , morphisms = StrictMap ; id/comp from Thm 2.5), every GExpr as an Endofunctor (gFunctor , via $\text{map_id}/\text{map_comp}/\text{map_isStrict}$), $\text{TexpF } \mathbb{N}$, the structure iso $\text{ExpIso} : T(\text{Exp}) \cong \text{Exp}$ (isoOfObjEq of Exp_structure_eq), and the algebra $\text{ExpAlg } \mathbb{N} \ h\mathbb{N} : \text{TAlgebra } (\text{TexpF } \mathbb{N})$. **Phase 3 DONE (existence of val):** the Kleene iteration $\text{descRel } (\text{val}_0 = \perp, \text{val}_{n+1} = \text{koT}(\text{val}_n) \circ j)$, $\text{descMap} = \bigcup_n \text{val}_n \ (\text{iSupMap})$, strict, with the fixed-point eq descMap_fix (uses $\text{GExpr.map_continuous}$) and homomorphism square descComm , packaged as $\text{descAlgHom} : \text{AlgHom } (\text{ExpAlg } \mathbb{N} \ h\mathbb{N}) \ B$ for any algebra B — Scott’s evaluation map. **Phase 4 DONE (uniqueness $\implies$ initiality):** $\text{algHom_fix}/\text{descMap_le_algHom}$ (val is the least hom), then the reverse via the **projection chain** $\rho_n = \text{i}_n \circ j_n$ ($\text{Subsystem.inj}/\text{proj}$ of $\text{expSub } n : \text{gTower}(\text{Texp } \mathbb{N}) \ n \triangleleft \text{Exp}$), $\text{rho_rel}/\text{rho_mono}/\text{iSupRho}$, $\text{iSupRho_eq_id} : \bigcup_n \rho_n = \text{I_Exp}$, $\text{rho_zero_rel } (\rho_0 = \perp)$. The **crux** $\text{GExpr.map_inj} : T.\text{map } h.\text{inj} = (T.\text{obj_subsystem } h).\text{inj} (+ \text{map_proj})$ by induction over the 6 constructors, with the 8 token lemmas $\text{sum}/\text{prod}/\text{oplus}/\text{otimesMapTok_inj} + \text{proj}$ discharging the binary cases; whence $\text{map_rho_eq} : T(\rho_n) = \text{i}'_n \circ j'_n$ and **key_rho** : $\rho_{n+1} = \text{expHom} \circ T(\rho_n) \circ \text{expInv}$. Then $\text{gcomp_rho_zero}/\text{succ}/\text{eq}$ give $\text{go } \rho_n = \text{descRel } n$ (g -independent, from the hom square + **key_rho**), so $\text{descMap_eq_algHom} : g.\text{hom}.1 = \text{descMap}$ (via iSupRho_eq_id), and with $\text{algHom_ext} \implies \text{ExpInitial} : \text{IsInitial } (\text{ExpAlg } \mathbb{N} \ h\mathbb{N})$ — Scott’s unique evaluation $\text{val}(s)$. Axiom audit $\subseteq \{\text{propext}, \text{Quot.sound}\}$ for the whole chain (Eq.le on Set was silently classical — use Eq.subset); full Domain green, zero sorry.

Exercise 6.24

- **Mathematical Target:** existence of domains satisfying given equations
- **Lean File:** Scott1980/Neighborhood/Exercise624.lean
- **Proof Notes:** the **double fixed-point** method for the coupled system $D \cong D + (D \times E)$, $E \cong D + E$. **Tokens decided:** both D, E are $\emptyset$ -free systems over the single type $\text{Str} = \{0, 1\}^*$ (Ex 6.19’s uniform category). Since $\text{sum} +$ and product $\times$ share the master shape $\{\Lambda\} \cup 0 \cdot (\dots) \cup 1 \cdot (\dots)$ over $\{0, 1\}^*$, the two token recursions are $\text{gTok } p \ q = \text{tok}(D + E) = \text{insert } \Lambda \ (0p \cup 1q)$ and $\text{fTok } p \ q = \text{tok}(D + (D \times E)) = \text{gTok } p \ (\text{gTok } p \ q)$. Both monotone ($\text{gTok_mono}/\text{fTok_mono}$) and **fully additive over a chain:** $\text{mem_gTok_iUnion}/\text{mem_fTok_iUnion}$ show every token of $*\text{Tok}(\bigcup_n) (\bigcup_n)$ lands in some single $*\text{Tok } a_n \ b_n$ — **each token references at most one coordinate**, even in fTok ’s nested $1(0p)$ branch, so no directedness merge is needed. **Double fixed point:** the pair Kleene iteration $\text{pIter} : \mathbb{N} \rightarrow \text{Set } \text{Str} \times \text{Set } \text{Str} \ (\Phi(p, q) = (\text{fTok } p \ q, \text{gTok } p \ q))$ from $(\{\Lambda\}, \{\Lambda\})$, with

component unions $\Gamma_D = \bigcup_n (\text{pIter } n).1$, $\Gamma_E = \bigcup_n (\text{pIter } n).2$; $\text{fTok_GammaD_GammaE} : \text{fTok } \Gamma_D \Gamma_E = \Gamma_D$ and $\text{gTok_GammaD_GammaE} : \text{gTok } \Gamma_D \Gamma_E = \Gamma_E$ ($\supseteq$ by $\text{fTok_mono} + \text{pIter_fst_subset_GammaD}$; $\subseteq$ by the additivity lemma landing at stage $n+1$). Capstone exists_double_fixedPoint. **Object level:** $\text{Dsol} = \{\Gamma_D\}$, $\text{Esol} = \{\Gamma_E\}$ (singletonSys), $\text{Fsol } D \ E = D.\text{sum } (D.\text{prod } E)$, $\text{Gsol } D \ E = D.\text{sum } E$; $\text{master_Fsol}/\text{master_Gsol}$ are rfl (masters expand to fTok/gTok), so $\text{Dsol_subsystem} : \{\Gamma_D\} \triangleleft D + (D \times E)$ and $\text{Esol_subsystem} : \{\Gamma_E\} \triangleleft D + E$ hold simultaneously (singleton-subsystem pattern as in 6.20). exists_simultaneous_subsystems packages both — **exactly the joint hypothesis of the simultaneous Theorem 6.14**, which then yields the two isos (matching the 6.20/6.21 precedent that delivers the $\triangleleft$ hypothesis “so 6.14 applies”). **Choice discipline:** avoid Set.subset_iUnion (it is classical) — use the choice-free $\text{pIter_}_ \text{subset_}$ via Set.mem_iUnion . Axiom audit $\subseteq \{\text{propext}, \text{Quot.sound}\}$.

Exercise 6.25

- **Mathematical Target:** projection-pair g, h identities on elements
- **Lean File:** `Scott1980/Neighborhood/Exercise625.lean`
- **Proof Notes:** `Exercise625.lean`, `ns Subsystem.ProjectionPair`. Galois conn. $\text{galois} : g(x) \sqsubseteq y \leftrightarrow x \sqsubseteq h(y)$ from the two elementwise laws $\text{proj_inj_apply} : h(g \ x) = x$ ($\leftarrow \text{toElementMap_comp} \circ \text{proj_comp_inj} \circ \text{toElementMap_idMap}$) and $\text{inj_proj_apply_le} : g(h \ y) \sqsubseteq y$ ($\text{le_iff_toElementMap_le.mp } \text{inj_comp_proj_le}$), $+ \text{toElementMap_mono}$. Extremal: $\text{proj_eq_sSup} : h(y) = \sqcup \{x \mid g(x) \sqsubseteq y\}$ ($\text{lowerSet} = \text{down-set of } h(y)$; lowerSet_bounded by $h(y)$, lowerSet_directed via $\text{top } h(y)$; antisymm w/ $\text{le_sSup}/\text{sSup_le}$) and $\text{inj_eq_sInf} : g(x) = \sqcap \{y \mid x \sqsubseteq h(y)\}$ ($\text{upperSet} = \text{up-set of } g(x)$; upperSet_nonempty contains $g(x)$; $\text{sInf}/\text{le_sInf}/\text{sInf_le}$). g preserves consistency $\text{inj_bounded} : D.\text{Bounded } S \rightarrow E.\text{Bounded } (g' \ S)$ ($\text{bound } g(b)$) and all lubs $\text{inj_sSup} : g(\sqcup S) = \sqcup (g' \ S)$ ($\sqsubseteq$ monotone; $\sqsubseteq$ via $\text{galois} + \text{sSup_le}$, each $g(s) \sqsubseteq \sqcup (g' \ S)$ by le_sSup). Choice-free $\{\text{propext}, \text{Quot.sound}\}$.

Exercise 6.26

- **Mathematical Target:** the lifting $\mathcal{D}_\perp$ over $\{0, 1\}^*$
- **Lean File:** `Scott1980/Neighborhood/Exercise626.lean`
- **Proof Notes:** `Exercise626.lean`, `ns Exercise619`. $\text{liftTok } D \ _hD = \{\{\Delta\} \cup 0\Delta\} \cup \{0X \mid X \in D\}$ ($\text{master liftTokMaster} = \text{insert } [] \ (0\Delta)$, proper $0X = \text{embBit false } X$), $\emptyset$ -free (liftTok_nonempty), packaged `ScottSys.lift`. **Elements** $|\mathcal{D}_\perp| \cong |\mathcal{D}|_\perp$: fresh bottom liftBot ($\text{mem} \leftrightarrow = \text{master}$), embedding $\text{liftUp } x$ ($\{\text{master}\} \cup \{0X \mid X \in x\}$); liftBot_le , $\text{liftUp_le_liftUp_iff}$ (order embedding), liftBot_lt_liftUp (strict, via $\text{embF_ne_liftTokMaster}$), $\text{unlift } z \ \text{hz}/\text{liftUp_unlift}$ (choice-free) and $\text{eq_liftBot_or_exists_liftUp}$ (covering, lone `Classical.choice` for the $z.\text{mem } 0\Delta?$ split). **Functor** (yes, strict): $\text{liftMapTok } f$ (rel : collapse-to-master row $\vee 0X \rightarrow 0X'$ from $f.\text{rel } X \ X'$), $\text{liftMapTok_isStrict}$ (any f), liftMapTok_id , liftMapTok_comp — mirrors sumMapTok with one summand. $\mathcal{D}_\perp \oplus \mathcal{E}_\perp \cong^D \mathcal{D} + \mathcal{E}$ ($\text{lift_oplus_lift_iso_sum}$): elementwise OrderIso to $\text{SumLift}/\text{fromSumLift}$ deleting the inner 0 ($00X' \leftrightarrow 0X', 10Y' \leftrightarrow 1Y'$), cross-tags vanish by $\emptyset$ -freeness — mirrors 6.19 $\text{toSum}/\text{fromSum}$. $\mathcal{D}_\perp \otimes \mathcal{E}_\perp \cong^D (\mathcal{D} \times \mathcal{E})_\perp$ ($\text{lift_otimes_lift_iso_lift_prod}$, answer to Scott’s ??): $\text{toLiftProd}/\text{fromLiftProd}$, $\text{prodTokNbhd}(0X') (0Y') \leftrightarrow 0$ ($\text{prodTokNbhd } X' \ Y'$), purely rectangular (no cross-empties). Helpers $\text{o_mem_embFF}/\text{TF}(_ \text{inv})$, $\text{ot_mem_prod}(_ \text{inv})$, $\text{lp_mem_embF}/\text{lp_prod_inv}$. NB: $\text{oplusTok}/\text{sumTok}$ membership lemmas need explicit $h_0 \ h_1/D_0 \ D_1$ (the .mem predicate drops the nonempty proofs under unification). Choice-free $\{\text{propext}, \text{Quot.sound}\}$ except the one covering lemma.

Exercise 6.27

- **Mathematical Target:** which subsystem relationships hold
- **Lean File:** Scott1980/Neighborhood/Exercise627.lean
- **Proof Notes:** Exercise627.lean, ns Exercise627. **Verdict:** first five hold for all $\mathcal{D}, \mathcal{E}$; the sixth $\mathcal{D} \trianglelefteq \mathcal{D} \otimes \mathcal{E}$ fails in general. $\trianglelefteq$ is Lemma 6.15's *embeds-as-subdomain* (Triangleleft); concrete $\{0,1\}^*$ constructors sumTok/prodTok/oplusTok/otimesTok (Ex 6.19/6.21) + function spaces funSpace/strictFun (FunctionSpace, Ex 5.10). (1) $(\mathcal{D} \otimes \mathcal{E}) \triangleleft (\mathcal{D} \times \mathcal{E})$ (otimesTok_subsystem_prodTok $\implies$ otimes_trianglelefteq_prod): smash is *literally* a subsystem — same master prodTokNbhd $\Delta_0 \Delta_1$, proper nbhds prodTokNbhd $X \times Y$ are a sub-family, intersections stay off the boundary (inter_ne_of_ne_left). (2) $\mathcal{D} \trianglelefteq \mathcal{D} \times \mathcal{E}$ (fst_trianglelefteq_prod): projection pair fstInj $X \mapsto (X, \Delta_1)$, fstProj via prodTokNbhd_subset_iff; fstProj $\circ$ fstInj = I, fstInj $\circ$ fstProj $\sqsubseteq$ I. (3) $(\mathcal{D} \oplus \mathcal{E}) \triangleleft (\mathcal{D} + \mathcal{E})$ (oplusTok_subsystem_sumTok $\implies$ oplus_trianglelefteq_sum): coalesced sum drops the improper copies $0\Delta_0, 1\Delta_1$; cross-tag intersections are empty hence not sum-nbhds. (4) $\mathcal{D} \trianglelefteq \mathcal{D} \oplus \mathcal{E}$ (inl_trianglelefteq_oplus): coalesced sum *glues bottoms*, so leftN $X = 0X$ (proper) / sumTokMaster ($X = \Delta_0$); projection pair inlInj/inlProj. The split $X = \Delta_0?$ is undecidable over an arbitrary system, so oplus_mem_leftN (and only it) uses Classical.em $\implies$ this part depends on Classical.choice (genuinely unavoidable at this generality; flagged). (5) $(\mathcal{D} \rightarrow \perp \mathcal{E}) \trianglelefteq (\mathcal{D} \rightarrow \mathcal{E})$ (strictFun_trianglelefteq_funSpace): inclusion $i = \text{inclMap}$ and *strictification* retraction $j = \text{strctMap}$ built by ofMono from the element-wise $\text{incl} = \text{toFilter} \circ \text{val} \circ \text{toStrictMap}$, $\text{strct} = \text{toStrictFilter} \circ \text{strictify} \circ \text{toApproxMap}$. New strictifyMap g (force $\Delta_0 \mapsto \Delta_1$): strictifyMap_le, strictifyMap_of_isStrict. Key toElementMap_inclMap/toElementMap_strctMap (the ofMono-on-principals union formulas, via mem_stepFun_iff/mem_sstepFun_iff); then strct_incl : strct $\circ$ incl = id and incl_strct_le : incl $\circ$ strct $\sqsubseteq$ id collapse cleanly using the equiv inverses (toApproxMap_toFilter/toStrictMap_toStrictFilter/...) + strictifyMap_le. Comp laws via a **choice-free** ext_of_principal (extracts mem from rel_dom, avoiding ext_of_toElementMap's by_cases) and le_iff_toElementMap_le. (6) $\neg(\mathcal{D} \trianglelefteq \mathcal{D} \otimes \mathcal{E})$ (not_trianglelefteq_otimes): counterexample $\mathcal{E} = \mathbb{N}$ (unitPt) — otimes_unitPt_collapse shows twoPt $\otimes \mathbb{N}$ has only its master, so subsingleton_element_of_only_master $\implies$ its element lattice is a point, but twoPt has two elements ($\{\square\}$ vs master), contradicting injectivity of the iso. Axiom audit: parts 1–3,5,6 $\subseteq$ {propext, Quot.sound}; part 4 adds Classical.choice (documented). Full Domain green, zero sorry.

Exercise 6.28

- **Mathematical Target:** (Plotkin) finite systems $\mathcal{D}, \mathcal{E}$
- **Lean File:** Scott1980/Neighborhood/Exercise628.lean
- **Proof Notes:** Exercise628.lean, ns Domain.Neighborhood. **Finite Cantor–Schröder–Bernstein:** if $|\mathcal{D}|, |\mathcal{E}|$ finite and $\mathcal{D} \trianglelefteq \mathcal{E} \trianglelefteq \mathcal{D}$ then $\mathcal{D} \cong \mathcal{E}$ (isomorphic_of_trianglelefteq_both); faithful “finite system” = finitely many nbhds version is isomorphic_of_finite_system (hyps NeighborhoodSystem.IsFinite := Finite $\{X // \mathcal{D}. \text{mem } X\}$, via finite_element_of_isFinite: $x \mapsto \{p | x. \text{mem } p. 1\}$ injects $|\mathcal{D}|$ into Set $\{X // \mathcal{D}. \text{mem } X\}$). **Crux:** $\trianglelefteq$ already gives an *order embedding* $|\mathcal{D}| \hookrightarrow |\mathcal{E}|$ (Trianglelefteq.elementEmbedding): unfold $\trianglelefteq$ to iso $e : |\mathcal{D}| \cong |\mathcal{D}'|$ onto $\mathcal{D}' \triangleleft \mathcal{E}$, take Prop 6.12's pair i, j ($\text{join} = I$), and projElementEmbedding $i \circ j$ is an embedding — monotone (toElementMap_mono) + order-reflecting via the monotone left inverse j ($i(a) \sqsubseteq i(b) \rightarrow j(i(a)) \sqsubseteq j(i(b)) \rightarrow a \sqsubseteq b$, using toElementMap_comp/hji/toElementMap_idMap); compose with e.toOrderEmbedding. Then orderIso_of_embeddings: mutual

order embeddings of *finite* types $\implies$ iso (f injective + `Fintype.card antisymm` $\implies$ `Fintype.bijective_iff_injective_and_card` $\implies$ f bijective; build `OrderIso` from `Equiv.ofBijective f hbij + f.map_rel_iff'` — partial-order safe, unlike `orderIsoOfSurjective` which needs `LinearOrder`). **Need the same for infinite systems? No** — the proof is a finite cardinality count with no infinite analogue (mutual retracts of infinite dcpos need not be isomorphic, Eilenberg-swindle obstruction); counterexample left as prose. Axioms: `projElementEmbedding, Trianglelefteq.elementEmbedding  $\subseteq$  {proptext, Quot.sound}`; `orderIso_of_embeddings, finite_element_of_isFinite` + main theorems add `Classical.choice` (extract `Fintype` from `Finite`; genuinely unavoidable). Full Domain green.

Exercise 6.29

- **Mathematical Target:** generalize $+$, $\times$ to infinitary operations
- **Lean File:** `Scott1980/Neighborhood/Exercise629.lean`
- **Proof Notes:** `Exercise629.lean`, ns `Exercise629`. **Verdict:** $+$, $\times$, $\oplus$ all generalize to an index family $D : \forall i, \mathcal{D}_i$ over α i ; $\otimes$ does NOT (infinite smash degenerates). Tokens: $\Sigma i, \alpha i$ (product-like) / `Option` ($\Sigma i, \alpha i$) (sum-like, none=basepoint). $\prod_i D_i$ (`iprod`): cylinders `iprodNbhd X = {p | p.2  $\in$  X p.1}` with $X i \in \mathcal{D}_i$ master off a finite support. Finite support is `FinSupp D X :=  $\exists l : \text{List } \iota, \forall i, i \notin l \rightarrow X i = \text{master}$` — the **positive List** form is the key choice-discipline move: it makes `FinSupp.inter` (master $\cap$ master outside $l++l'$) and reconstruction `z_mem_of_slices` constructive (the negative form $X i \neq \text{master} \rightarrow i \in l$ needs DNE on undecidable set-equality $\rightarrow$ `Classical.choice`). Headline **infinitary Prop 3.2:** `iprodEquiv :  $|\prod_i D_i| \simeq \prod_i |D_i|$` (pointwise order), via `proj/fromPi` round-trips `fromPi_toPi/proj_fromPi` + slice reconstruction `z_mem_iprodNbhd_restrictTo` (`List.rec` over support) and `iprodNbhd_injective`. $\sum_i D_i$ (`isum`): basepoint master `sumMasterI` or one tagged copy `injI i X` (single coordinate $\implies$ no support condition). `isum_trichotomy` ($\perp$ or exactly one summand), `isum_summand_unique`. $\oplus_i D_i$ (`ioplus`): as $\sum$ minus improper copies ($X \neq \text{master}$) — generalizes fine. $\otimes_i D_i$ (`iotimes`): proper = *every* coordinate proper, which over infinite ι contradicts finite support $\implies$ `iotimes_only_master/iotimes_subsingleton`: only the basepoint survives (one-point domain). **Choice-discipline GOTCHAs:** (a) `Function.update_eq_self` is classical — prove `updTuple D i master = ( $\cdot$  master)` by `funext+by_cases`; (b) avoid `by_cases` on index $i=j$ in `injI`-intersection `inter_mem` proofs — recover $i=j$ constructively from the consistency witness `index_of_some_mem_injI`; (c) `Mathlib's Set.Finite/Function.update_eq_self/List.mem_toFinset/Finite.of_fintype` all pull `Classical.choice`. **Axioms:** data `iprod, isum, ioplus, iotimes, iprodEquiv` and `isum_summand_unique` all $\subseteq$ {proptext, Quot.sound}; only `isum_trichotomy` (excluded middle: reaches-a-summand?) and the degeneracy `iotimes_subsingleton` (cardinality via classical `Set.Finite`) add `Classical.choice` — both Prop-level and flagged. Full Domain green, zero sorry.

3.7 Lecture VII: Computability in Effectively Given Domains

Lecture VII establishes the recursion-theoretic foundations of domain theory.

Definition 7.1

- **Mathematical Target:** a *computable presentation* of a neighbourhood system
- **Lean File:** `Scott1980/Neighborhood/Definition71.lean`

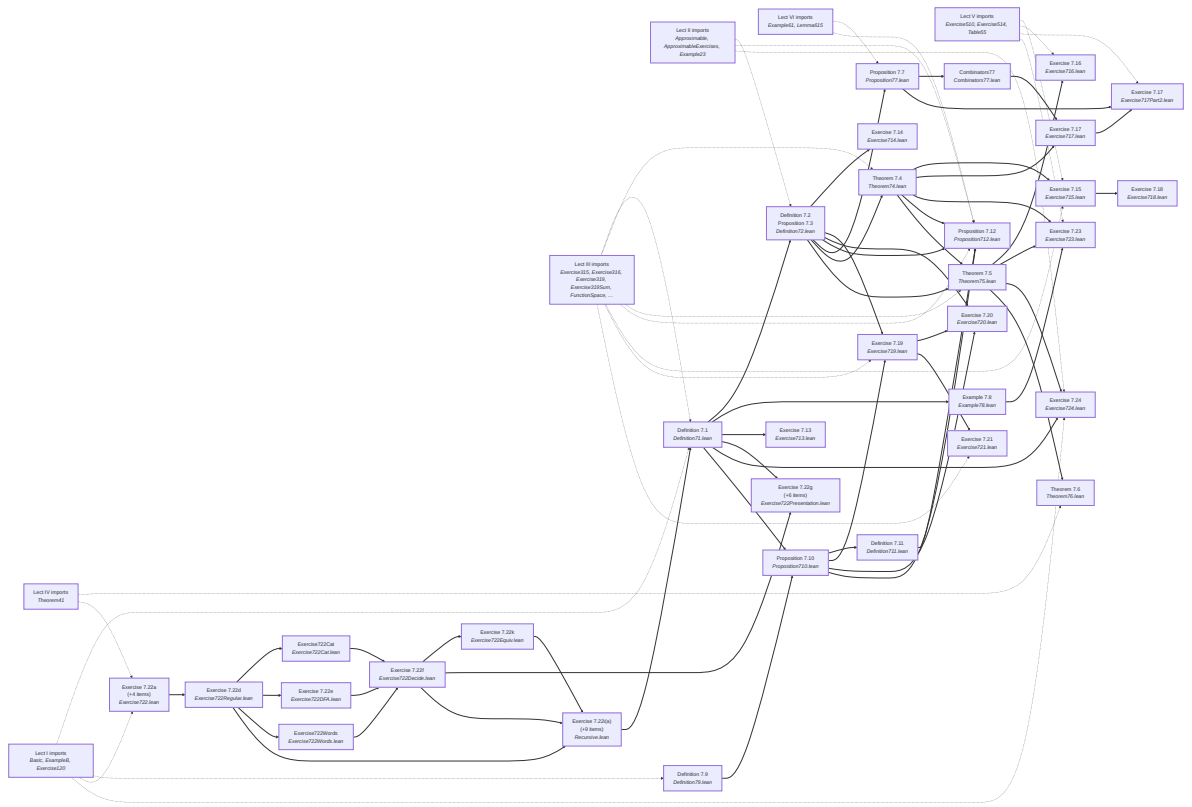

Figure 8: Lean module dependencies for Lecture VII: Computability in Effectively Given Domains.

- Proof Notes:** `Definition71.lean` (+ `Recursive.lean`), `ns Domain.Neighborhood`. `ComputablePresentation V`: enumeration $X: \mathbb{N} \rightarrow \text{Set } \alpha$ with `mem_X` (each $X_n \in \mathcal{D}$) + `surj` (onto $\mathcal{D}$), and Scott's two relations as **bespoke choice-free** recursively-decidable predicates over the integer indices (tuples coded by `Nat.pair`): (i) `interEq_computable` : `RecDecidable3` (`fun n m k ↦ Xn ∩ Xm = Xk`) and (ii) `cons_computable` : `RecDecidable2` (`fun n m ↦ ∃ k. Xk ⊆ Xn ∩ Xm`). Only X is data; the rest are `Prop`. Scott's biconditional $X_n \subseteq X_m \leftrightarrow X_n \cap X_m = X_n$ gives `incl_computable` (`reindex (n,m) ↦ (n,m,n)` via `RecDecidable.comp` + `Set.inter_eq_left`), and $X_n = X_m \leftrightarrow X_n \subseteq X_m \wedge X_m \subseteq X_n$ gives `eq_computable` (`RecDecidable.and` of `incl` with its `swapPair reindex` + `Set.Subset.antisymm_iff`). `NeighborhoodSystem.IsEffectively V := Nonempty (ComputablePresentation V)`; sanity inhabitant `unitSys_isEffectivelyGiven` (`unitPresentation`, constant $X_n = \Delta = \text{univ}$, both relations always-true via the constant-1 decider `recDecidable_of_forall`). **Recursion-theory note** — we roll our own and rejected `Mathlib` here because it opens `Classical` and we are avoiding that: `Mathlib`'s `ComputablePred/Primrec/Partrec` correctness lemmas are proved with `grind/lia` or the `@[simp] Nat.unpair_pair`, all of which pull `Classical.choice` (even `Computable.const` does). So we modelled “recursively decidable” as `Domain.Recursive.RecDecidable p := ∃ f, Nat.Primrec f ∧ ∀ n, p n ↔ f n = 1` and rebuilt the needed slice choice-free in `Recursive.lean`: choice-free `Nat.sqrt` correctness (`sqrt_le/lt_succ_sqrt/sqrt_eq_of`, porting `iter_sq_le/lt_iter_succ_sq` with `grind/lia` → `omega`), the `Nat.pair/unpair` round-trips (`unpair_pair/pair_unpair`), and primitive-recursive `id/+/*` (`primrec_id/primrec_add/primrec_mul`, via the choice-free `Nat.Primrec constructors`). Result: **#print axioms of `incl_computable/eq_computable/unitPresentation/unitSys_isEffectivelyGiven` is {`propext`, `Quot.sound`}** — genuinely choice-free, no `Classical.choice`.

Definition 7.2

- **Mathematical Target:** *computable map* between recursively presented domains
- **Lean File:** Scott1980/Neighborhood/Definition72.lean
- **Proof Notes:** Definition72.lean, ns Domain.Neighborhood. **IsComputableMap** $P \ Q$ $f := \text{REPred}_2 (\text{fun } n \ m \mapsto f.\text{rel } (X_n) \ (Y_m))$: relative to computable presentations P of V , Q of W (Def 7.1), an **ApproximableMap** $f : V \rightarrow W$ is *computable* iff its neighbourhood relation $X_n \ f \ Y_m$, transported to integer indices, is **recursively enumerable**. **IsComputableElement** $Q \ y := \text{REPred} (\text{fun } m \mapsto y.\text{mem } (Y_m))$ is Scott’s *computable element* (the $\mathbb{N} \rightarrow W$ degeneration: the index set $\{m \mid Y_m \in y\}$ is r.e.). Proved: **idMap_isComputable** (identity is computable — the identity half of Prop 7.3 — since $X_n \ I \ X_m \leftrightarrow X_n \subseteq X_m$ is **incl_computable**, recursively *decidable* hence r.e. via **RecDecidable.re**), and **principal_isComputableElement** (every finite/principal element $\uparrow X_n$ is computable, since its index set $\{m \mid X_n \subseteq X_m\}$ is a recursive slice of **incl_computable** — reindex $m \mapsto \langle n, m \rangle$ by the choice-free **Nat.Primrec.const n |>.pair primrec_id**; Scott: “if y were finite, the set of indices would be recursive”). **Recursion-theory (choice-free, in Recursive.lean)**: modelled “recursively enumerable” as a **projection of a recursively decidable relation** — **REPred** $p := \exists q, \text{RecDecidable } q \wedge \forall n, p \ n \leftrightarrow \exists i, q \langle i, n \rangle$ (the projection form represents the empty set too, unlike Scott’s bare enumerator description $y = \{Y_{\{r(i)\}}\}$; equivalent), **REPred**₂ its **Nat.pair**-coding; **RecDecidable.re/RecDecidable2.re** (drop the search var via **unpair.2** reindex, witness $i=0$), **REPred.of_iff** (transfer across $\leftrightarrow$), **rePred_of_forall**. #print axioms: **IsComputableMap/IsComputableElement/REPred/REPred.of** iff depend on **no axioms**; **idMap_isComputable/principal_isComputableElement/RecDecidable.re** of_forall are {propext, Quot.sound} — genuinely choice-free, no **Classical.choice**.

Proposition 7.3

- **Mathematical Target:** identity is computable; computable maps compose
- **Lean File:** Scott1980/Neighborhood/Definition72.lean
- **Proof Notes:** Definition72.lean, ns Domain.Neighborhood. Both halves + Scott’s stated consequence. **idMap_isComputable** (identity computable — $X_n \ I \ X_m \leftrightarrow X_n \subseteq X_m$, recursively decidable hence r.e.). **comp_isComputable** ($hf : \text{IsComputableMap } P \ Q \ f, hg : \text{IsComputableMap } Q \ R \ g \implies \text{IsComputableMap } P \ R \ (g.\text{comp } f)$): $X_n (g \circ f) Z_k \leftrightarrow \exists Y, X_n \ f \ Y \wedge Y \ g \ Z_k$, and $Q.\text{surj}$ makes the middle Y range over indices l ($Y=Y_l$, recovered from $g.\text{rel_dom}$), giving $\exists l, X_n \ f \ Y_l \wedge Y_l \ g \ Z_k$, r.e. by the new closure lemmas. **apply_isComputableElement** (the “immediate and useful consequence”: f computable + x computable element $\implies f(x)$ computable element; $f(x) = \{Y_m \mid \exists X_n \in x, X_n \ f \ Y_m\}$, $P.\text{surj}$ ranges X over n , r.e. by closure). **New choice-free r.e. closure layer in Recursive.lean** (projection-of-RecDecidable form): **REPred.comp** (reindex by a **Nat.Primrec** g : absorb g along **unpair.2**), **REPred.and** (pair the two search vars i, j into one w ; decider via **RecDecidable.and** of two reindexed deciders), **REPred.proj** (p r.e. $\implies \text{fun } n \mapsto \exists i, p \langle i, n \rangle$ r.e.; fold i into the search var). Composition assembles as $((hf.\text{comp } hgf).\text{and } (hg.\text{comp } hgg)).\text{proj}$ with **primrec** reindexers $u \mapsto \langle u.2.1, u.1 \rangle$, $u \mapsto \langle u.1, u.2.2 \rangle$ (built from **Nat.Primrec.left/right/comp/pair**). #print axioms of **comp_isComputable/apply_isComputableElement/REPred.comp/.and/.proj** all {propext, Quot.sound} — choice-free.

Theorem 7.4

- **Mathematical Target:** $D_0 + D_1$ and $D_0 \times D_1$ are effectively given if D_0, D_1 are
- **Lean File:** Scott1980/Neighborhood/Theorem74.lean

- **Proof Notes:** Theorem74.lean, ns Domain.Neighborhood. **Product half (done):** `prodPresentation P0 P1` is a `ComputablePresentation` of `prod V0 V1` (over $\alpha \oplus \beta$, `Product.lean`) with $W_k = X^0_{\{k.unpair.1\}} \cup X^1_{\{k.unpair.2\}}$ (Scott's $r = \text{Nat.pair}$, $p, q = \text{unpair.1/2}$). The product is uniform (no tag analysis), so 7.1(i)/(ii) each split via `prodNbhd_inter/prodNbhd_subset_iff` into a **conjunction** of the two factors' `interEq/cons` relations on reindexed indices — recursively decidable by `RecDecidable.and/.comp/.of_iff` (no new RT). **prod_isEffectivelyGiven.** Combinators: `proj0_isComputable/proj1_isComputable` ($(X^0_n \cup X^1_m) p_i Z \leftrightarrow (\text{component}_i) \subseteq Z$, a recursive slice of `incl_computable`, Scott's worked example for `proj1`); `paired_isComputable` ($Z_n \langle f, g \rangle (X^0_k \cup X^1_l) \leftrightarrow Z_n f X^0_k \wedge Z_n g X^1_l$, conjunction of two r.e.); `prodMap_isComputable` ($f \times g$ computable, via $f \times g = \langle f \circ p_0, g \circ p_1 \rangle$ (Ex 3.19) + `comp_isComputable` (Prop 7.3)). All $\subseteq \{\text{propext}, \text{Quot.sound}\}$. **New choice-free RT layer in Recursive.lean (for the + half):** `primrec_pred/primrec_sub` (truncated subtraction via `prec`, `mathlib`'s are classical); `RecDecidable.natEq` ($\{0,1\}$ -char $1 - ((a-b) + (b-a))$); biconditional split into two *omega implications* since `omega` on an $\leftrightarrow$ pulls `Classical.choice!`; `RecDecidable.not`; `RecDecidable.em` (decidability of an RD predicate, via `Nat.decEq` — `eq_or_ne` is classical); `RecDecidable.or` (choice-free De Morgan $p \vee q \leftrightarrow \neg(\neg p \wedge \neg q)$ using `.em`); `REPred.or` (disjunction of r.e. is r.e.: witness carries a $\{0,1\}$ tag selecting the disjunct). **Sum half (done):** `sumPresentation P0 P1` over `Option( $\alpha \oplus \beta$ )` (`Exercise318.lean`) with a `Nat.pair` tag enumeration `sumEnum` (`tag 0  $\mapsto$  inj0 X0{k.2}`, `tag 1  $\mapsto$  inj1 X1{k.2}`, `tag  $\geq 2 \mapsto$  sumMaster`). Equality of two `sumNbhd`s decoded by `sumEnum_eq_iff` $\rightarrow$ recursively decidable `eqSEdec`; the `interEq/cons` deciders are a 9-branch (`tag_a  $\times$  tag_b`, with a 3-way `tag_c` split where needed) intersection-table case analysis ($M \cap M = M$ via `sumMaster_inter_sumEnum`, $L \cap L \rightarrow P_0.interEq$, $L \cap R = \emptyset$ impossible by nonemptiness, ...) assembled from `RecDecidable.or/.not/.and/.natEq`. **sum_isEffectivelyGiven.** Combinators: `inMap0/1_isComputable` ($X^0_n \text{ in }_0 Z_m \leftrightarrow \text{inj}_0 X^0_n \subseteq Z_m$, tag-decoded), `outMap0/1_isComputable` ($Z_n \text{ out}_0 X^0_m \leftrightarrow \text{leftPart } Z_n \subseteq X^0_m$, where `leftPart` is $X^0_{\{n.2\}}$ on a left copy and Δ_0 (master index k_0) elsewhere), `sumMap_isComputable` ($f+g$ computable directly: its relation tag-decodes to a 3-way disjunction — codomain master, or both-left+f, or both-right+g — r.e. by `REPred.or`). Needs the $\forall X, V.\text{mem } X \rightarrow X.\text{Nonempty}$ hyps that `sum` requires. **Choice-discipline note:** `omega` on a *non-arithmetic* goal (e.g. a `Set` equality, even when closing it by a contradiction in the $\mathbb{N}$ hyps) silently pulls `Classical.choice` — must `exfalse` first; likewise avoid `Set.Nonempty.ne_empty` (classical), derive $x \in \emptyset$ via `Set.notMem_empty`.

Theorem 7.5

- **Mathematical Target:** $(D_0 \rightarrow D_1)$ is effectively given; `eval/curry` computable; computable elements = computable maps
- **Lean File:** `Scott1980/Neighborhood/Theorem75.lean`
- **Proof Notes:** Theorem75.lean (+ `Recursive.lean`), ns Domain.Neighborhood. **Math core (Prop 3.9(i), choice-free):** a function-space `nbhd` $\bigcap [X_i, Y_i]$ is non-empty iff for every sublist-selection whose inputs share a lower `nbhd` in $\mathcal{D}_0$ the selected outputs are consistent in $\mathcal{D}_1$; modelled over **coded entry-lists** (`funPair P0 P1 e = (X0{e.1}, Y1{e.2})`, `funListOf`, `stepFun_funListOf_nonempty_iff`), with the reverse built via `leastMap` + the **choice-free** $\mathcal{D}_0$ -inclusion test (`P0.incl_computable.em`, replacing the library `rel_interYs`'s classical `by_cases X  $\subseteq$  X1`). The consistency decision principle `consChain_iff` (a single `inter-fold idxchain` + one bounded inclusion check — since $X_{\{\text{idxchain}\}}$ is always a `nbhd`) packages choice-free into `funCons_decidable` via a single-pass fold `consFold` over `decodeList c` threading the subset bitmask (`read %2/halved`), wrapped in `RecDecidable.bForall` (bound 2^c). **Inclusion** `stepFun(funListOf ea)  $\subseteq$  stepFun(funListOf`

eb) characterised by `stepFun_funListOf_subset_iff` (forward tests `leastMap`; backward uses the choice-free `rel_interYs_funList`), packaged into `subChar` (a conditional-`inter` foldCode computing `interYsIdx`). **Milestone 6** — `funPresentation P0 P1 gN incl0 incl1 eq1 ...` (`ComputablePresentation (funSpace V0 V1)`): enumeration `Xenum c` = if `gN c=1` then `stepFun(funListOf(decodeList c))` else `univ` (junk codes → master, keeping it choice-free *data*); `interEq/cons` via `interEqChar/consPairChar` (consistency of the `appendCode`), `eqEnumChar` (`subChar` both ways, guarded by `gN/trivialChar`), `inter=interIdx` (`appendCode`, `stepFun_funListOf_appendCode`), `masterIdx=0` (`Xenum 0=univ`); `funSpace_isEffectivelyGiven` extracts the concrete `incl0/incl1/eq1/fc0/fc1` chars from `P0/P1` inside the `Prop` goal. **Milestone 7** — `evalMap_isComputable`: (`Xenum c, X0j`) `eval Y1m ↔ ∀f∈Xenum c, f X0j Y1m ↔ Xenum c ⊆ [X0j, Y1m]` (`evalMap_rel_prodNbhd_iff`), and `[X0j, Y1m] = Xenum(⟨⟨j,m⟩, 0⟩+1)` (`Xenum_singleton`, a one-entry always-consistent code), so `eval` is the **decidable** `funPresentation.incl_computable` reindexed by a `primrec` singleton-code map (Scott’s “`eval` is a recursive set”), hence r.e. **Milestone 8** — `Xenum_isComputableElement_iff/isComputableElement_funPresentation_iff`: `φ ⊃ Xenum c ↔ (gN c=1 → ∀e∈decodeList c, φ ⊃ [X0{e.1}, X1{e.2}])` (`mem_Xenum_iff`, via `mem_stepFun_iff`); element-side $\implies$ map-side reindexes by the single-step code, map-side $\implies$ element-side guards the bounded- $\forall$ by decidable `gN c=1` (`Decidable.imp_iff_not_or`). **Milestone 9** — `curry_isComputable`: (`X0n`) `curry(g) (Xenum c) ↔ (gN c=1 → ∀⟨j,k⟩∈decodeList c, X0n ∪ X1j g X2k)` (`curry_rel_Xenum_iff`, via `mem_Xenum_iff_map+gSection_rel`), a **parameterised** bounded- $\forall$ over the coded list, r.e. by `REPred.forall_mem_decodeList2`, guarded by consistency. **New choice-free RT in Recursive.lean**: `REPred.forall_mem_decodeList` (bounded $\forall e \in \text{decodeList } c, p \ e$ of r.e. `p` is r.e. — the finite witness tuple is packed into one search code `w` threaded by the `{0,1}` fold `reForallChar`), and its parameterised form `REPred.forall_mem_decodeList2` ($\forall e \in \text{decodeList } t.2, p \ t.1 \ e$, reduced to the former by primitively re-coding the list into the pairs $\langle t.1, e \rangle$ via `mapPairCode/mapPairStp`). `#print` axioms of `funSpace_isEffectivelyGiven/evalMap_isComputable/Xenum_isComputableElement_iff/curry_isComputable` (+ all helpers and both RT closures) is `{propext, Quot.sound}` — genuinely choice-free. **Choice gotcha**: the keystone `(stepFun L).Nonempty ↔ ∀X, V1.mem(interYs Δ1 L X)` via `rel_interYs` pulls `Classical.choice` (undecidable `X ⊆ p.1 by_cases`); fixed by phrasing 3.9(i) over explicit finite selections and using the presentation’s decidable inclusion. Also `Eq.le/.ge` on `Set` equalities route through the classical `Preorder` instance — use `Eq.subset/Eq.superset`.

Theorem 7.6

- **Mathematical Target:** `fix : (D → D) → D` is computable on effectively given `D`
- **Lean File:** `Scott1980/Neighborhood/Theorem76.lean`
- **Proof Notes:** `Theorem76.lean`, ns `Domain.Neighborhood`. **`fixMap_isComputable`:** relative to the function-space presentation `funPresentation P P ...` (Theorem 7.5) and `P`, the combinator `fixMap : (D → D) → D` (Theorem 4.2) is computable. Scott reads `fix` off the fixed-point construction: $\bigcap [X_{\{n_i\}}, X_{\{m_i\}}] \text{ fix } X_{\ell} \leftrightarrow \exists$ a finite sequence $\Delta = X_{\{k_0\}}, \dots, X_{\{k_p\}}$ with each $\bigcap \{X_{\{m_i\}} | X_{\{k_j\}} \subseteq X_{\{n_i\}}\} \subseteq X_{\{k_{j+1}\}}$ — an $\exists$ -of-decidable, hence r.e. (genuinely r.e., not recursive: no length bound). **Math core (`fixMap_rel_iff`, choice-free):** the `funSpace nbhd F=Xenum c` has least map $\hat{g} = \text{toApproxMap}(\uparrow F)$; `rel_iff_mem_principal+fixMap_toElementMap+mem_fixElement` reduce `(fixMap V).rel (Xenum c) (Xℓ)` to $\exists n, (\hat{g}^n).rel \Delta \ X_{\ell}$. The one-step $\hat{g}.rel \ (X_a)(X_b) \leftrightarrow Xenum \ c \subseteq [X_a, X_b]$ (`leastMap_Xenum_rel`) is **recursively decidable**, since $[X_a, X_b] = Xenum(\text{codePair } a \ b)$ (one-entry always-consistent code, `Xenum_codePair/Xenum_singleton`), so the test is the decidable `funSpace` inclusion `Xenum c ⊆ Xenum(codePair a b)` (`funPresentation.incl`

computable). A finite $\mathbf{g}$ -chain is modelled by an index **list** ($\mathbf{gStepsOK}/\mathbf{gLastOf}$, intermediate nbhds named via $\mathbf{P.surj}$); $\mathbf{gStepsOK_sound}/\mathbf{gStepsOK_complete}$ (induction on $\mathbf{list}/\mathbf{n}$ using $\mathbf{iter_comm}$'s $(\mathbf{g}^n).comp \ \mathbf{g}$ form) give $\mathbf{fixElement_mem_iff_chain}$: $\mathbf{g.fixElement.mem}(\mathbf{X}_\ell) \leftrightarrow \exists \mathbf{full}, \mathbf{gStepsOK} \ \mathbf{g} \ \mathbf{P} \ \mathbf{masterIdx} \ \mathbf{full} \wedge \mathbf{X}_{\{\mathbf{gLastOf}\}} \subseteq \mathbf{X}_\ell$ (relaxed $\subseteq$ end-point handles the $\mathbf{n}=0$ base via upward closure). **r.e. packaging:** the $\exists \mathbf{full}$ is realised as the r.e. $\exists i, q(\text{pair } i \ n) \text{ — } q$ decodes i , runs a single primrec $\mathbf{foldCode}(\mathbf{fixChainChar}, \text{step } \mathbf{fixStp}/\mathbf{fixPStep})$ threading the previous index and a $\{0,1\}$ consistency flag, and checks the flag ($\mathbf{fixPStep_foldl_snd}$) AND the final inclusion $\mathbf{incl}(\text{pair } \mathbf{lastIdx} \ \ell)=1$ ($\mathbf{P.incl_computable}$). $\mathbf{chainDec_iff_gStepsOK}$ bridges the fold's flag-chain ($\mathbf{chainDec}$) to $\mathbf{gStepsOK}$; $\mathbf{fixChainChar_spec}$ reads off $\mathbf{.unpair.1}=\mathbf{lastIdx}$, $\mathbf{.unpair.2}=\mathbf{flag}$. Reuses Theorem 7.5's $\mathbf{Xenum}/\mathbf{funPresentation}/\mathbf{Xenum_singleton}$ and $\mathbf{Recursive.lean}$'s $\mathbf{foldCode}/\mathbf{selectFn}$. **no new recursion theory needed.** $\mathbf{\#print} \ \mathbf{axioms} \ \mathbf{fixMap_isComputable}/\mathbf{fixMap_rel_iff}/\mathbf{fixElement_mem_iff_chain}/\mathbf{fixChainChar_spec}$ is $\{\mathbf{propext}, \mathbf{Quot.sound}\}$ — genuinely choice-free.

Proposition 7.7

- **Mathematical Target:** $\mathbf{D}\S$ is effectively given; the Example 6.1 combinators are computable
- **Lean File:** $\mathbf{Scott1980}/\mathbf{Neighborhood}/\mathbf{Proposition77.lean}$
- **Proof Notes:** $\mathbf{Proposition77.lean} + \mathbf{Combinators77.lean}$, ns $\mathbf{Domain.Neighborhood.Proposition77}$ green, wired. **Clause 2 — combinators (Milestone 4, $\mathbf{Combinators77.lean}$):** Scott treats “a selection”. $\lambda x. x^\S = \mathbf{inSharpMap} : \mathbf{ApproximableMap} \ \mathbf{D} \ (\mathbf{Dsharp} \ \mathbf{D} \ \mathbf{hD})$, relation $\mathbf{X} \ (\lambda x. x^\S) \ \mathbf{W} \leftrightarrow 0 \cdot \mathbf{X} \subseteq \mathbf{W} \ (\mathbf{embZero} \ \mathbf{X} \subseteq \mathbf{W})$; $\mathbf{inSharpMap_toElementMap}$ proves its elementwise action is Example 6.1's $\mathbf{inSharp}$. **$\mathbf{inSharp_isComputable}$:** index relation $\mathbf{embZero}(\mathbf{X}_n) \subseteq \mathbf{V}_m \leftrightarrow \mathbf{V}_{\{2n+1\}} \subseteq \mathbf{V}_m$, i.e. $\mathbf{dsharpPresentation.incl_computable}$ reindexed by primrec $(n, m) \mapsto (2n+1, m)$, hence r.e. **$\mathbf{proj}_0$** (first projection of the pair part) = $\mathbf{proj0Map} : \mathbf{ApproximableMap} \ (\mathbf{Dsharp} \ \mathbf{D} \ \mathbf{hD}) \ (\mathbf{Dsharp} \ \mathbf{D} \ \mathbf{hD})$, relation $\mathbf{W} \ \mathbf{proj}_0 \ \mathbf{Z} \leftrightarrow \mathbf{Z} = \Gamma \vee \exists \mathbf{P} \ \mathbf{Q}, \ \mathbf{W} = 1 \cdot \mathbf{P} \cup 2 \cdot \mathbf{Q} \wedge \mathbf{P} \subseteq \mathbf{Z}$; $\mathbf{proj0_toElementMap_pairSharp}$ proves $\mathbf{proj}_0(\langle x, y \rangle^\S) = x$. **$\mathbf{proj0_isComputable}$:** $\mathbf{proj0_rel_Vsharp_iff}$ reduces the index relation to $k=0 \vee (m\%2=0 \wedge m \neq 0 \wedge \mathbf{V}_{\{(m/2-1).unpair.1\}} \subseteq \mathbf{V}_k)$ — disjunction of the equality decider ($k=0$), parity deciders ($\%2, \neq 0$), and $\mathbf{incl_computable}$ reindexed by the primrec left-child map, all recursively decidable so .re. The $\mathbf{ApproximableMap}$ *data* and *both faithfulness theorems* audit $\subseteq \{\mathbf{propext}, \mathbf{Quot.sound}\}$; $\mathbf{inSharp_isComputable}/\mathbf{proj0_isComputable}$ use $\mathbf{Classical.choice}$ (via $\mathbf{incl_computable}/\mathbf{set}$ reasoning). **Clause 1 — $\mathbf{D}\S$ effectively given (Milestones 1–3, $\mathbf{Proposition77.lean}$):** $\mathbf{dsharp_isEffectivelyGiven} \ \mathbf{P} \ \mathbf{hD}$: if $\mathbf{D}$ is effectively given ($\mathbf{ComputablePresentation} \ \mathbf{D}$) then so is $\mathbf{Dsharp} \ \mathbf{D} \ \mathbf{hD}$ (Example 6.1's $\mathbf{D}\S \cong \mathbf{D} + (\mathbf{D}\S \times \mathbf{D}\S)$), via $\mathbf{dsharpPresentation} \ \mathbf{P} \ \mathbf{hD} : \mathbf{ComputablePresentation} \ (\mathbf{Dsharp} \ \mathbf{D} \ \mathbf{hD})$. Enumeration $\mathbf{Vsharp} \ \mathbf{D} \ \mathbf{P}$ of $\mathbf{MemS}$ nbhds over carrier $\mathbf{List} \ \mathbf{Bool} \times \alpha$ ($\mathbf{V}_0 = \Gamma$ master $\mathbf{masterIdx}=0$; odd $2n+1 \mapsto \mathbf{embZero}(\mathbf{X}_n)$ leaves; even $2n+2 \mapsto \mathbf{embPair} \ \mathbf{V}_{\{n.1\}} \ \mathbf{V}_{\{n.2\}}$ nodes); choice-free $\mathbf{mem_X}/\mathbf{surj}/\mathbf{nonempty} + \mathbf{per}$ -parity $\cap$ -identities. **Deciders are primitive-recursive course-of-values on $\mathbf{w}=\text{pair } n \ m$** , built by a **generic memo evaluator** (prototyped locally, not yet promoted to $\mathbf{Recursive.lean}$): $\mathbf{listGet} \ \mathbf{c} \ \mathbf{i} = (\mathbf{decodeList} \ \mathbf{c}).\mathbf{getD} \ \mathbf{i} \ 0$, reverse memo table $\mathbf{rtbl} \ \text{step}(\mathbf{rtbl}(\mathbf{w}+1)=\text{pair}(\text{step}(\text{pair } \mathbf{w} \ (\mathbf{rtbl} \ \text{step } \mathbf{w}))) \ (\mathbf{rtbl} \ \text{step } \mathbf{w})+1), \mathbf{gOf} \ \text{step } \mathbf{w} = \text{step}(\text{pair } \mathbf{w} \ (\mathbf{rtbl} \ \text{step } \mathbf{w}))$, with $\mathbf{listGet_rtbl} : \mathbf{v} < \mathbf{w} \rightarrow \mathbf{listGet} \ (\mathbf{rtbl} \ \text{step } \mathbf{w}) \ (\mathbf{w}-1-\mathbf{v}) = \mathbf{gOf} \ \text{step } \mathbf{v}$ (strong induction). **$\mathbf{dsharpStep}$ fcons $\mathbf{feq} \ \mathbf{finter}$** computes a **packed triple** $\mathbf{packT} \ (\mathbf{eqBit})(\mathbf{consBit})(\mathbf{interIdx})$ in one pass (accessors $\mathbf{eqB}/\mathbf{consB}/\mathbf{intI}$, 9 parity cases via $\mathbf{selectFn}$, no if; primrec $\mathbf{dsharpStep}$). Heart: **$\mathbf{dsharp_decider_spec}$** — strong induction on $\text{pair } i \ j$ (well-founded by $\mathbf{pair_lt_pair_of_lt}$) proving simultaneously $\mathbf{consB}=1 \leftrightarrow \exists l, \mathbf{V}_1 \subseteq \mathbf{V}_i \cap \mathbf{V}_j, \mathbf{Vsharp}(\mathbf{intI} \dots) = \mathbf{V}_j$ (when consistent), $\mathbf{eqB}=1 \leftrightarrow \mathbf{V}_i = \mathbf{V}_j$; uses $\mathbf{memS_sub_embZero}/\mathbf{memS_sub_embPair}/\mathbf{Vsharp}$

eq_Gamma_iff inversions. Assembly: `dsharp_intI_correct` (inter-idx correctness, `fcons/feq` irrelevant — instantiated `fun _ => 0`), `dsharp_interEq_iff` (7.1(i): $V_n \cap V_m = V_k \leftrightarrow \text{consB} \cdot \text{eqB}(\text{intI}, k) = 1$) bundled with `cons_computable` from `dsharp_decider_spec` and `inter n m = intI(gOf(dsharpStep 0 0 P.inter))(pair n m)`). **Axioms:** all *data* ($V_{\text{sharp}}/dsharpStep/gOf/intI \subseteq \{\text{propxt}, \text{Quot.sound}\}$) the Prop-level correctness (`dsharp_decider_spec/dsharp_intI_correct/dsharp_isEffectivelyGiven`) pulls `Classical.choice` — **unavoidable** (reasons about Set equality/subset over an arbitrary carrier α with no `DecidableEq`).

Example 7.8

- **Mathematical Target:** the powerset PN is effectively given
- **Lean File:** `Scott1980/Neighborhood/Example78.lean`
- **Proof Notes:** `Example78.lean`, ns `Domain.Neighborhood.Example78`, green, wired. Scott’s finite-set enumeration $E_n = \{k \mid \exists i, j. i < 2^k \wedge n = i + 2^k + j \cdot 2^{k+1}\}$ is exactly “ k is a set bit of n ” (`Nat.testBit n k`); neighbourhoods are the cofinite sets $\text{nbhd } n = \mathbb{N} \setminus E_n = \{k \mid n.\text{testBit } k = \text{false}\}$ ($\text{nbhd } 0 = \mathbb{N} = \Delta$, `nbhd_zero`). `nbhd_inter`: $\text{nbhd } n \cap \text{nbhd } m = \text{nbhd } (n \mid \mid m)$ (Scott’s $E_n \cup E_m = E_k$, via `Nat.testBit_lor + Bool.or_eq_false_iff`); `nbhd_injective` (`Nat.eq_of_testBit_eq`). The system PN over tokens $\mathbb{N}$ (`mem Y := ∃ n, Y = nbhd n`, master $\Delta = \mathbb{N}$) is closed under $\cap$ by `nbhd_inter`, so *any two neighbourhoods are consistent* (`PN_consistent`). `PNpres : ComputablePresentation PN`: enumeration `nbhd`; intersection function = the bespoke **choice-free primitive-recursive bitwise OR Recursive.myLor** (`= (· ||| ·)` by `myLor_eq_lor`, `primrec_myLor`); relation 7.1(i) $\text{nbhd } n \cap \text{nbhd } m = \text{nbhd } k \leftrightarrow n \mid \mid m = k$ decided by `RecDecidable.natEq` (equality of two `primrec` fns + `nbhd_injective`); 7.1(ii) consistency is always-true (`recDecidable_of_forall`). `PN_isEffectivelyGiven`. New RT layer in `Recursive.lean`: `myLor a b` iterates `lorStep` (strip the low bit of each arg, OR them, accumulate with a doubling weight) $a+b$ times; correctness via the invariant `lorStep_iter_spec` (`acc + 2^k · (a/2^k ||| b/2^k) = a ||| b`) + the one-step law `lor_low_rec` and `lowOr/lowOr_eq_mod`; `primrec_myLor` is built from `Nat.Primrec.prec` (`rec_const_iterate`). All audit $\subseteq \{\text{propxt}, \text{Quot.sound}\}$ (the only omega-on $\leftrightarrow$ choice trap in `lowOr_eq_mod` is avoided by an explicit `Nat.mod_two_eq_zero_or_one` case split).

Definition 7.9

- **Mathematical Target:** the power domain PD
- **Lean File:** `Scott1980/Neighborhood/Definition79.lean`
- **Proof Notes:** `Definition79.lean`, ns `Domain.Neighborhood.NeighborhoodSystem`, green, wired. The **Smyth power domain** $\mathbb{PD}$: Scott’s down-set $\downarrow X = \{Y \in \mathcal{D} \mid Y \subseteq X\}$ is *exactly* Exercise 1.20’s **upSet**, and the preparation $\mathcal{D}^\dagger = \{\downarrow X \mid X \in \mathcal{D}\}$ is *exactly* Ex 1.20’s **powerSystem** (aliased **dagger**; `dagger_isomorphic :  $\mathcal{D} \cong \mathcal{D}^\dagger$` reuses `isomorphic_powerSystem`). The neighbourhood family `PDmem W := ∃ L : List (Set α), (∀ X ∈ L, D.mem X) ∧ W = ⋃ {X ∈ L} ↓X` (finite unions of down-sets; empty list `[]` $\implies$ empty union $\emptyset$, Scott’s `n=0`). Membership facts: `mem_PDunion` ($z \in \bigcup \{X \in L\} \downarrow X \leftrightarrow \exists X \in L, z \in \downarrow X$), `PDmem_empty` ($\emptyset \in \mathbb{PD}$), `PDmem_upSet` (each $\downarrow X \in \mathbb{PD}$, $X \in \mathcal{D}$), `PDmem_master` ($\downarrow \Delta = \mathcal{D} \in \mathbb{PD}$), `PDmem_union` (closed under binary—hence finite—union, via list `++`). `PDmem_iff_fin` rewrites the family with Scott’s $\bigcup_{i < n}$ (a `Fin n → Set α`), equivalent via `List.ofFn/List.get`. The two displayed remarks: `upSet_inter_nonempty_iff` ($\downarrow X \cap \downarrow Y \neq \emptyset \leftrightarrow \{X, Y\}$ consistent, i.e. $\exists Z \in \mathcal{D}, Z \subseteq X \cap Y$) and `dagger_upSet_inter` (consistent case: $\downarrow X \cap \downarrow Y = \downarrow (X \cap Y) \in \mathcal{D}^\dagger$); the unconditional $\downarrow X \cap \downarrow Y = \downarrow (X \cap Y)$ is Ex 1.20’s `upSet_inter`. This is everything Scott states *as part of Definition 7.9 itself*

(the family + its two displayed remarks); that $\mathbb{PD}$ is *itself a neighbourhood system*, effectively given when $\mathcal{D}$ is, is the separate **Proposition 7.10** — its own row below, and no longer deferred (`Proposition710.lean`, green, zero sorry). Choice-discipline: the empty/singleton membership proofs use explicit cases `hX` on $X \in []$ and `Set.notMem_empty / List.mem_singleton` (NOT simp, which here pulls `Classical.choice`); all decs audit `{propxt, Quot.sound}`.

Proposition 7.10

- **Mathematical Target:** $\mathbb{PD}$ is a neighbourhood system, effectively given if $\mathcal{D}$ is
- **Lean File:** `Scott1980/Neighborhood/Proposition710.lean`
- **Proof Notes:** `Proposition710.lean`, ns `Domain.Neighborhood.NeighborhoodSystem`, green, wired. **Part A** `PowerDomain : NeighborhoodSystem (Set  $\alpha$ ) (mem:=PDmem, master:= $\downarrow\Delta$ )`. Closure under $\cap$ (`PDmem_inter`) reduces, after distributing $\cap$ over the finite unions (`upSetUnion_cons`, `Set.*_inter_distrib_*`), to the single term $\downarrow X \cap \downarrow Y = \downarrow (X \cap Y)$ (Ex 1.20 `upSet_inter`): if $X \cap Y \in \mathcal{D}$ it is one down-set (`PDmem_upSet`), else $\downarrow (X \cap Y) = \emptyset$ (`PDmem_empty`) since `inter_mem` forces any $Z \subseteq X \cap Y$ to witness $X \cap Y \in \mathcal{D}$. The split by `cases V.mem (X  $\cap$  Y)` is the **sole Classical step**, genuinely unavoidable (membership in an arbitrary system is not decidable) and confined to the `inter_mem` **Prop** field — the data fields `mem/master` are choice-free. **Part B** `PowerDomain_isEffectivelyGiven : V.IsEffectivelyGiven  $\rightarrow$  V.PowerDomain.IsEffectivelyGiven`, via `PDPresentation` (parametrised on $\mathcal{D}$'s primrec consistency decider `cons`, extracted choice-free from `P.cons_computable` inside the `Nonempty` proof). Enumeration `Ypd c :=  $\bigcup_{a \in \text{decodeList } c} \downarrow X_a$` (`Ypd 0 =  $\emptyset$` , `Ypd  $\langle v, \text{acc} \rangle + 1 = \downarrow X_v \cup \text{Ypd acc}$`), surjective onto `PDmem` (`PDmem_exists_Ypd`). Relation (i): $Y_c \subseteq Y_k \leftrightarrow \forall a \in \text{dl } c, \exists b \in \text{dl } k, X_a \subseteq X_b$ (`Ypd_subset_iff`) is `RecDecidable2` by new choice-free bounded $\forall/\exists$ -over-`decodeList` combinators `RecDecidable2.bForallList/bExistsList` in `Recursive.lean` over `P.incl_computable`; equality `eqCode_computable` is the anti-symmetric $\wedge$. The **intersection code** `interCode cons n m` is a nested `foldCode` (outer over `dl n`, inner over `dl m`) prepending `P.inter a b` exactly on consistent pairs (`isOne (cons  $\langle a, b \rangle$ )`); `interCode` is axiom-free, `primrec_interCode  $\subseteq$  {propxt, Quot.sound}`, correctness `Ypd_interCode : Y_{interCode n m} = Y_n  $\cap$  Y_m` by `Ypd_innerstep/Ypd_innerfold1/Ypd_outerfold1`. `cons_computable` for $\mathbb{PD}$ is trivial ($\emptyset \in \mathbb{PD} \implies$ every pair consistent, witness code 0). The bundled defs carry `Classical.choice` only through `Prop` fields ($\subseteq$ {`propxt`, `Quot.sound`} for `Ypd/interCode/primrec_interCode/subCode_computable`).

Definition 7.11

- **Mathematical Target:** finite-element joins $\{x_0, \dots, x_{n-1}\}$ in the power domain
- **Lean File:** `Scott1980/Neighborhood/Definition711.lean`
- **Proof Notes:** `Definition711.lean`, ns `Domain.Neighborhood.NeighborhoodSystem`, green, wired. Scott's $\{x_0, \dots, x_{n-1}\} = \{z \in \mathbb{PD} \mid \exists X_i \in x_i. \bigcup_{i < n} (\uparrow X_i) \subseteq z\}$ formalized as a filter `PDfinJoin n xs : V.PowerDomain.Element (n=0  $\implies$  PDfinJoinZero =  $\perp$ ;  $n \geq 1 \implies$  PDfinJoinSucc)`. Membership `PDmemFinJoin:  $W \in \{xs\} \leftrightarrow \exists (X_i \in x_i). \text{PD.mem } W \wedge \forall i. \downarrow X_i \subseteq W$` (Scott's union read as down-sets via `upSet`); `PDmem_finJoin_iUnion` rewrites the $\forall i$ conjunct as $\bigcup_{i < n} \downarrow X_i \subseteq W$. Unary `PDsingleton x = PDfinJoin 1 ! $[x]$` with `PDmem_singleton`. Filter axioms (`master_mem/inter_mem/up_mem`) proved choice-free ($\subseteq$ {`propxt`, `Quot.sound`}; intersection step uses Ex 1.20 `upSet_inter`). $\{\uparrow X\} = \uparrow(\downarrow X)$ (`PDsingleton_principal`) proved in **Prop 7.12**.

Proposition 7.12

- **Mathematical Target:** the union mapping on the power domain
- **Lean File:** Scott1980/Neighborhood/Proposition712.lean
- **Proof Notes:** Pass (A/B/D proved; $C = D \leq \mathbb{P}D$ REFUTED with formalized counterexample) — Proposition712.lean, ns Domain.Neighborhood.NeighborhoodSystem (+ counterexample ns Domain.Neighborhood.Counterexample712C), green, wired, zero sorry. **Part A:** $\text{PDsingletonApproxMap}$ (ofMono on $\uparrow X \mapsto \{\uparrow X\}$) with $\text{PDsingletonApproxMap_toElementMap}$ ($(\lambda x. \{x\})(x) = \{x\}$) and $\text{PDsingleton_principal}$ ($\{\uparrow X\} = \uparrow(\downarrow X)$ on finite elements). **Part B:** filter meet PDsingletonMeet ; binary intersection law $\text{PDfinJoin_pair} / \text{PDfinJoin_inter_two}$ ($\{x, y\} = \{x\} \cap \{y\}$); binary approximable map $\text{PDfinJoinApproxMap}_2$ + product packaging finJoinMap_prod (ofMap₂). **Part C** ($D \leq \mathbb{P}D$) is FALSE in general (it holds iff $|D|$ has a greatest element, e.g. $\emptyset \in D$): **vshape_not_trianglelefteq_powerDomain** : $\neg(\text{Vshape} \trianglelefteq \text{Vshape.PowerDomain})$ for the flat two-point domain Vshape (Bool-tokens $\{\text{univ}, \{\text{true}\}, \{\text{false}\}\}$, $\{\text{true}\} \cap \{\text{false}\} = \emptyset \notin D$). Invariant: **HasTop** (greatest element); $\mathbb{P}D$ is *unconditionally* $\cap$ -closed (empty union always a witness, PDmem_inter) so $|\mathbb{P}D|$ has a top (**improperTop/hasTop_of_inter_closed/powerDomain_hasTop**); $\triangleleft$ inherits $\cap$ -closure (**subsystem_inter_closed**) and $\cong^D$ transports **HasTop** (**hasTop_of_iso**), so $D \leq \mathbb{P}D \implies \text{HasTop } D$ (**hasTop_of_trianglelefteq_powerDomain**); but Vshape has two incomparable maximal points, **Vshape_not_hasTop**. The surviving injection half is $\text{PDsingletonApproxMap}$. **Part D:** against PDPresentation , **singleton_isComputable** ($\exists b \in d_1 \ k, X_n \subseteq X_b$ via $\text{incl_computable.swap.bExistsList.swap}$) and $\text{PDfinJoinApproxMap}_2$ **isComputable** (two independent singleton tests, proj_0 -style reindexing). Audited: data $\text{Vshape/improperTop}$ choice-free ($\subseteq \{\text{propext}, \text{Quot.sound}\} / \text{none}$); A/B/D + counterexample-Prop decs $\subseteq \{\text{propext}, \text{Quot.sound}, \text{Classical.choice}\}$ (inherited from $\text{PowerDomain.inter_mem}$).

Exercise 7.13

- **Mathematical Target:** effectively given domain $\leftrightarrow$ an $\text{INCL}(n, m)$ relation on integers
- **Lean File:** Scott1980/Neighborhood/Exercise713.lean
- **Proof Notes:** Exercise713.lean, ns Domain.Neighborhood.Exercise713, green, wired, zero sorry. The abstract data **InclStructure** carries $\text{INCL} : \mathbb{N} \rightarrow \mathbb{N} \rightarrow \text{Prop}$ with $\text{INCL}/\text{CONS}/\text{MEET}$ recursively decidable ($\text{RecDecidable}_2/\text{RecDecidable}_2/\text{RecDecidable}_3$), a primrec meet function meetIdx + master code topIdx (faithful “effective” witnesses of Scott’s $\exists$ -axioms (iii)/(iv), mirroring how $\text{ComputablePresentation}$ carries inter as primrec data), reflexivity/transitivity, topIdx_spec , meetIdx_spec ; derived $\text{CONS } n \ m := \exists k, \text{INCL } k \ n \wedge \text{INCL } k \ m, \text{MEET } n \ m \ k := \forall j, \text{INCL } j \ k \leftrightarrow (\text{INCL } j \ n \wedge \text{INCL } j \ m)$, Scott’s axioms restated as **axiom_i..axiom_iv**. ($\Leftarrow$) Scott’s hint system $\text{toNbhd } n = \{m \mid \text{INCL } m \ n\}$ with key law **toNbhd_subset_iff** : $S_n \subseteq S_k \leftrightarrow \text{INCL } n \ k$ ($\rightarrow$ via $n \in S_n$ by (i); $\leftarrow$ by (ii)); **toSystem** (master $\Delta = \mathbb{N} = S_{\text{topIdx}}$ by toNbhd_top ; inter_mem from (iv) via MEET) and **toPresentation** make it effectively given (**toSystem_isEffectivelyGiven**): rel 7.1(i) $S_n \cap S_m = S_k \leftrightarrow \text{MEET } n \ m \ k$ (**toNbhd_inter_eq_iff**, decided by meet_dec), rel 7.1(ii) consistency $\leftrightarrow \text{CONS}$ (cons_dec , via **toNbhd_subset_inter_iff**), $\text{inter} := \text{meetIdx}$, $\text{masterIdx} := \text{topIdx}$. ($\Rightarrow$) **ofPresentation** P turns any $\text{ComputablePresentation } V$ into an InclStructure with $\text{INCL } n \ m := X_n \subseteq X_m$: refl/trans of $\subseteq$, $\text{topIdx} := \text{masterIdx}$ ($X_n \subseteq \Delta$), $\text{meetIdx} := P.\text{inter}$; INCL/CONS deciders are $P.\text{incl_computable}/P.\text{cons_computable}$, and MEET decidability is the key lemma **meet_iff_interEq** : $\text{MEET}(n, m, k) \leftrightarrow X_n \cap X_m = X_k$ ($\Rightarrow$ a MEET witness at $j=k$ makes (n, m) consistent $\implies X_n \cap X_m \in \mathcal{D}$ by inter_mem , surj enumerates it $\implies X_n \cap X_m \subseteq X_k$; $\Leftarrow$ **subset_inter_iff**) composed with $P.\text{interEq_computable}$. **Round-trip A ofPresentation_toPresentation_INCL** ($\text{INCL} \mapsto \mathcal{D} \mapsto \text{INCL}$ recovers INCL exactly, via

toNbhd_subset_iff). **Round-trip B** answers “is this essentially *any* effectively given system?” with **yes**: **reconstruct_isomorphic** : toSystem (ofPresentation P) $\cong^D$ V built from the mutually-inverse, order-preserving **reconElem** ($\{S_n | X_n \in x\}$) / **reconElemInv** ($\{X_n | S_n \in y\}$) packaged as **reconIso** : $|V| \simeq_o |reconstruct\ P|$ (powerIso-style; reconElemInv.inter_mem derives V-consistency from the S-meet index $p \in S_p \subseteq S_n \cap S_m \implies X_p \subseteq X_n \cap X_m$). **ofPresentation_toNbhd_eq_iff** : $S_n = S_m \leftrightarrow X_n = X_m$ glues the iso. The Ex-7.18 *effective* isomorphism would tighten “essentially”. Choice-discipline win: toNbhd_inter_eq_iff uses **exact iff_comm** (NOT **tauto**, which silently pulls **Classical.choice**), so **all** decls — data and Prop — audit $\subseteq \{\text{propext}, \text{Quot.sound}\}$.

Exercise 7.14

- **Mathematical Target:** (recursion theorists) r.e. facts after Def 7.2; computable elements
- **Lean File:** Scott1980/Neighborhood/Exercise714.lean
- **Proof Notes:** Exercise714.lean, ns Domain.Neighborhood.Exercise714, green, wired, zero sorry. **Half 1** — “non-empty r.e. $\Leftrightarrow$ range of a primrec function”: **repred_range_primrec** (range of primrec r is r.e.: $r\ i = n$ is $\text{RecDecidable.natEq}, \exists i, r\ i = n$ its projection) and converse **repred_exists_primrec_range** (a non-empty $\text{REPred } p$ with witness a is enumerated by r $w := \text{selectFn } (\text{isOne } (qc\ w))\ w.2\ a$ — returns n on a witnessing code $w = \langle i, n \rangle$, else the fall-back $a \in p$; non-emptiness is exactly what the fall-back needs). Map form **repred2_exists_primrec_enum** ($p\ n\ m \leftrightarrow \exists i, s\ i = n \wedge r\ i = m$ for primrec s, r , Scott’s $f = \{(X_{\{s(i)\}}, Y_{\{r(i)\}})\}$: split the range fn of the Nat.pair -coded relation). **Half 2** — **computableElement_eq_decreasing_iUnion_principal**: every computable element y ($\text{IsComputableElement } Q\ y$) is $y = \bigcup_i \uparrow Y_{\{t(i)\}}$ with $t: \mathbb{N} \rightarrow \mathbb{N}$ **primrec** and **decreasing** $Q.X(t(i+1)) \subseteq Q.X(t\ i)$. The index set $\{m | Y_m \in y\}$ is r.e. + non-empty (contains Δ by $y.\text{master_mem}$), so Half 1 lists it as range of primrec r_0 ; running intersections $t\text{Fun } Q\ r_0\ (t\ 0 = r_0\ 0, t(i+1) = Q.\text{inter } (t\ i)\ (r_0(i+1)))$, primrec via Nat.Primrec.prec give the decreasing chain — still in y (filter $\cap$ -closed), still cofinal ($Q.X(t\ i) \subseteq Q.X(r_0\ i)$), so $\bigcup \uparrow$ is unchanged. **All four headline decls audit** $\subseteq \{\text{propext}, \text{Quot.sound}\}$ (Half 2 too).

Exercise 7.15

- **Mathematical Target:** finish 7.4 for $D_0 \otimes D_1, D_0 \oplus D_1, D_\infty$
- **Lean File:** Scott1980/Neighborhood/Exercise715.lean
- **Proof Notes:** Exercise715.lean, ns Domain.Neighborhood, green, wired, zero sorry. All three constructs effectively given. $\otimes / \oplus$ use **Scott’s bare Definition 7.1** (**ScottPresentation** = **ComputablePresentation** minus the primrec inter field), because the bottom-collapse makes a primrec inter provably impossible (deciding $Xb = \Delta_0?$ is r.decidable but not primrec): **smash smash_isEffectivelyGivenS** (**smashEnum**/**smashPresentation**; relations (i),(ii) reduce to the components’ deciders + properness tests; only the enumeration branches classically) and **coalesced osum_isEffectivelyGivenS** (**osum** : **NeighborhoodSystem** (**Option** ($\alpha \oplus \beta$))), **osumEnum**/**osumPresentation**; (i) reduces to **sumPresentation.interEq** via a primrec reindex, (ii) by direct case analysis). $D_\infty = \text{iterSys } V$ is **uniform** (no deletion) so it carries the project’s *full* **ComputablePresentation** and is **iterSys_isEffectivelyGiven** — fully choice-free $\subseteq \{\text{propext}, \text{Quot.sound}\}$, **data and proofs**. A D_∞ -code t codes a finite fiber-index list (**Recursive.decodeList**); fiber $j = P.X\ (\text{iterIdx } t\ j)$ with $\text{iterIdx } t\ j := \text{nthCode } t\ j\ P.\text{masterIdx}$ (default Δ beyond length). Relations (i),(ii) reduce to bounded coordinate checks over $j < n+m(+k)$

(iterEnum_inter_eq_iff/iterEnum_cons_iff + RecDecidable.bForall); the **inter** function iterInter tabulates $P.inter$ coordinate-wise via tabCode; masterIdx:=0 (empty list $\implies$ all- Δ); surj by exists_list_fiber (induction building the index list). **Combinator:** projN_isComputable — the coordinate projections projN n (Ex 3.16; head=projN 0) are computable ($W(\text{projN } n) \times \leftrightarrow X_{\{\text{iterIdx } t \ n\}} \subseteq X_b$, a slice of incl_computable). New choice-free infra in Recursive.lean: nthCode (list-code indexing, nthCode_eq via foldCode/nthCode_foldl), tabCode (tabulation via Nat.Primrec.prec, decodeList_tabCode/tabCode_nth_lt/tabCode_nth_ge), and **choice-free re-proofs of the grind-tainted List.getD lemmas** (getD_eq_default_cf/getD_append_cf/getD_append_right_cf/getD_map_range_cf/getD_eq_getElem_cf) — the latter are what keep D_∞ at $\subseteq \{\text{propxt}, \text{Quot.sound}\}$. **ALL combinators DONE — full Theorem-7.4 parity** (each *_isComputable via IsComputableMapS): $\oplus$ osumInMap_{0/1} (in), osumOutMap_{0/1} (out, via leftPart/rightPart), osumMap ($f \oplus g$; rel = codomain-master collapse $\vee$ proper inj₀-pair $\cdot f.rel \vee$ proper inj₁-pair $\cdot g.rel$; helpers osum_eq_master_of_inj_{0/1} master, osum_mem_subset_inj_{0/1}); $\otimes$ smashProj_{0/1} (proj — same Sum.inl⁻¹' $W \subseteq X$ ' relation as product proj, computable via smashEnum_eq_eff+incl_computable), smashPaired ($\langle a, b \rangle \otimes$ strict pairing — proper image factors else master; computability is raw-index $\neg \text{proper}(m) \vee (\text{proper}(m) \wedge a.rel \wedge b.rel)$, no eff bridge), smashMap ($f \otimes g$). **Axioms:** projN_isComputable $\subseteq \{\text{propxt}, \text{Quot.sound}\}$; the $5 \oplus + 3 \otimes$ combinators = $\{\text{propxt}, \text{Classical.choice}\}$ (Classical.choice Prop-level only, inherited from the classical osumEnum/smashEnum properness branch — *data* stays choice-free).

Exercise 7.16

- **Mathematical Target:** curry as a neighbourhood relation: recursive or r.e.?
- **Lean File:** Scott1980/Neighborhood/Exercise716.lean
- **Proof Notes:** Exercise716.lean, ns Domain.Neighborhood, green, wired, zero sorry, fully choice-free $\subseteq \{\text{propxt}, \text{Quot.sound}\}$ (*data and proofs*). **Answer:** curry is a *recursive* (recursively decidable) set, not merely r.e. — exactly as Scott shows for eval. Reuses Table 5.5's combinator curryC $V_0 \ V_1 \ V_2 = \text{ofIso}(\text{curryIso} \dots)$ (Thm 2.7 on Thm 3.12's order-iso; faithfulness curryC_toApproxMap) rather than redefining. (1) **curry written out as a relation between neighbourhoods (curryComb_rel):** $G \text{ curryC } H \leftrightarrow \text{mem } G \wedge \text{mem } H \wedge \forall g \in G, \text{curry } g \in H$. Forward uses the *least map* toApproxMap $\uparrow G$ of G (new lemma toApproxMap_principal_mem — $\uparrow G$'s least map lies in G), monotonicity of curryEquiv, and up-closure of H ; backward applies the hypothesis to that least map. (2) **Recursive decidability (curryComb_rel_recDecidable/curryComb_isComputable):** relative to the Thm-7.5 function-space presentations $PA = (D_0 \times D_1 \rightarrow D_2)$, $PB = (D_0 \rightarrow (D_1 \rightarrow D_2))$, inner $Pc = (D_1 \rightarrow D_2)$, the relation on codes is $X_{PA} \ n \ \text{curryC} \ X_{PB} \ m \leftrightarrow gNb \ m=1 \rightarrow \forall e \in \llbracket m \rrbracket, gNc \ e_2=1 \rightarrow \forall e' \in \llbracket e_2 \rrbracket, X_{PA} \ n \subseteq X_{PA}(\text{curryStepCode } e_1 \ e')$. Each $X_{PA} \ n \subseteq X_{PA}(\text{step } \langle X_{\{e_1\}}, Y_{\{e'_1\}} \rangle Z_{\{e'_2\}})$ is product-function-space inclusion (incl_computable, recursively *decidable*); the step is a one-entry Xenum-singleton (curryStepCode, primrec via primrec_curryStepCode); the two $\forall$ s are *bounded* over decodeList (RecDecidable₂.bForallList), the gN-guards via RecDecidable.natEq + Decidable.imp_iff_not_or. Reductions: mem_Xenum_iff_map, curry_rel_Xenum_iff, Xenum_singleton, prodPresentation_X. Concludes IsComputableMap PA PB (curryC ...) via RecDecidable₂.re.

Exercise 7.17

- **Mathematical Target:** finish 7.7 for $D\S$; strict $g:D\S \rightarrow E$
- **Lean File:** Scott1980/Neighborhood/Exercise717.lean

- **Proof Notes:** `Exercise717.lean` (Part 1) + `Exercise717Part2.lean` (Part 2), ns Domain.Neighborhood/...`Exercise717`, green, wired, zero sorry. **Clause 1 of 7.17 = all Example 6.1 combinators of $D\mathbb{S}$ computable** (Scott prints “6.2”; it’s 6.1, matching 7.7’s own statement). `Combinators77.lean` did the selection `inSharp( $\lambda x.x\mathbb{S}$ ) + proj0`; this file adds the rest: `proj1Map` (pair-part 2nd projection $D\mathbb{S} \rightarrow D\mathbb{S}$; `proj1_toElementMap_pairSharp : $\text{proj1}(\langle x,y \rangle \mathbb{S}) = y$; proj1_isComputable — index rel $k=0 \vee (m \text{ even} \neq 0 \wedge V_{\{q(m/2-1)\}} \subseteq V_k$), the right-child mirror of proj0) and pairSharpMap (the joint pairing constructor pair : $D\mathbb{S} \times D\mathbb{S} \rightarrow D\mathbb{S}$ as ApproximableMap (prod (Dsharp) (Dsharp)) (Dsharp); rel $V \ W \leftrightarrow \text{mem } V \wedge \text{mem } W \wedge \exists A \ B, V = \text{prodNbhd } A \ B \wedge \text{embPair } A \ B \subseteq W$; pairSharpMap_toElementMap : $\text{pair}(x,y) \mapsto \langle x,y \rangle \mathbb{S} = \text{Example61.pairSharp}$; pairSharp_isComputable — index rel reduces to $V_{\{2 \cdot t+2\}} \subseteq V_k$ via Vsharp_even, a slice of dsharpPresentation. computable reindexed by primrec $s \mapsto \langle 2 \cdot s.1+2, s.2 \rangle$). With inSharpMap/proj0Map this is the full combinator set of $D\mathbb{S} \cong D + (D\mathbb{S} \times D\mathbb{S})$ (injections in_pair + projections proj0, proj1). Data + both faithfulness thms $\subseteq \{\text{propext}, \text{Quot.sound}\}$; the 2*_isComputable carry Classical.choice (set reasoning over arbitrary α , inherited from incl_computable — same as Combinators77). Part 2 (Exercise717Part2.lean): E eff. given (pres. Q) + computable $u : D \rightarrow E, v : E \times E \rightarrow E \implies$ the unique strict catamorphism $g : D\mathbb{S} \rightarrow E$ ($g(\text{in } x) = u(x)$, $g(\text{pair } y \ z) = v(g \ y, g \ z)$) is computable. Built g as a neighbourhood relation GRel u v (inductive: $\Gamma \mapsto \Delta_E, 0 \cdot X \mapsto u, 1 \cdot P \cup 2 \cdot Q \mapsto \exists Z_1 Z_2, P \ g \ Z_1 \wedge Q \ g \ Z_2 \wedge \langle Z_1, Z_2 \rangle v \ Z \rightarrow \text{ApproximableMap } gMap$ (no separate top-clause: gRel_master = GRel.gamma rfl); inversion lemmas gRel_{gamma, embZero, embPair}_inv (need hD + Classical); faithfulness gMap_in/gMap_pair + gMap_strict (all $\subseteq \{\text{propext}, \text{Quot.sound}\}$). Computability gMap_isComputable: the index rel GRel(V_n)(Y_m) is r.e. via a certificate evaluator gEval = gOf(gStep ...) (a fresh course-of-values memo over $w = \langle n, \text{cert} \rangle$, distinct from dsharpStep since the same sub-nbhd may fold to different outputs in different tree positions, so the cert mirrors the derivation tree). cert decodes to $\langle \text{out}, \text{wit}, \text{lcert}, \text{rcert} \rangle$; gStep branches on the Vsharp shape $(0/2a+1/2a+2)$ emitting $\langle \text{okBit}, \text{out} \rangle$, node reading children from the memo table via listGet_rtbl. Needed Nat.pair monotonicity (pair_lt_pair_left/pair_le_pair_right/pair_lt_pair_of_lt_le + new le_pair_left in Recursive.lean) for the child-code $\leq w$ measure. gEval_sound/gEval_complete (strong induction on w/n) give GRel(V_n)(Y_m) $\leftrightarrow \exists \text{cert}, gEval \langle n, \text{cert} \rangle . \text{ok} = 1 \wedge Y_{\{\text{cert.out}\}} = Y_m$; deciders fe/fU/fV read off $Q.\text{eq_computable}$ and the r.e. relations of u/v (prodPresentation_X aligns v ’s domain $\langle k1, k2 \rangle \mapsto \text{prodNbhd}(Y_{\{k1\}})(Y_{\{k2\}})$), then RecDecidable.and/.re/REPred.proj iff. Data+equations $\subseteq \{\text{propext}, \text{Quot.sound}\}$; gMap_isComputable carries Classical.choice (inherited from the GRel inversion lemmas’ set reasoning over arbitrary α, β — same as Part 1’s *_isComputable). set_option maxHeartbeats 1000000 on gEval_complete (giant decoded-cert terms).`

Exercise 7.18

- **Mathematical Target:** define *effective isomorphism*; $\text{effective } D_\infty \cong (D_\infty)_\infty$
- **Lean File:** `Scott1980/Neighborhood/Exercise718.lean`
- **Proof Notes:** `Exercise718.lean`, ns Domain.Neighborhood.`Exercise718`, green, wired, zero sorry. **Part 1** — “complete the sentence”: **EffectiveIso $P \ Q$** = a pair of mutually inverse approximable maps `toMap : $D \rightarrow E$, invMap : $E \rightarrow D$, both computable (IsComputableMap, Def 7.2), with invMap o toMap = I_D, toMap o invMap = I_E; EffectivelyIsomorphic $P \ Q$:= Nonempty (EffectiveIso P Q). Derives a domain iso EffectiveIso.toDomainIso : $|D| \cong_o |E|$ (elementwise maps inverse via toElementMap_comp/toElementMap_idMap, monotone via toElementMap_mono) $\implies$ EffectivelyIsomorphic.isomorphic : $D \cong^D E$ (tightens Def 1.9’s $\cong$; with Ex 7.13’s reconstruct_isomorphic, tightens “essentially the same”). Part 2 — $D_\infty \cong (D_\infty)_\infty$ effective: the index reindexing $x_k \leftrightarrow x_{\{\text{unpair}$`

$k\}} (x_{\{i,j\}} = x_{\text{pair } i \ j})$. Double-indexed fiber $\text{fiber2 } S \ i \ j := \text{fiber } (\text{fiber } S \ i) \ j$; forward/inverse maps $\text{Fmap } (W \ F \ S \leftrightarrow \forall i \ j, \text{fiber } W \ (\text{pair } i \ j) \subseteq \text{fiber2 } S \ i \ j) / \text{Gmap } (S \ G \ W \leftrightarrow \forall k, \text{fiber2 } S \ (\text{unpair } k) \subseteq \text{fiber } W \ k)$. Inverse laws $\text{Gmap_comp_Fmap}/\text{Fmap_comp_Gmap}$ proved directly on the relations via the reindex constructions $\text{reindexF}/\text{reindexG}$ ($\text{reindexF_subset_iff}/\text{reindexG_subset_iff}$, membership $\text{reindexF_mem}/\text{reindexG_mem}$). The reindexG cofinite- Δ bound uses a **choice-free** Prop-level induction $\text{exists_inner_bound}$ for the uniform inner $\max$ + a local strict $\text{pair_lt_pair_of_lt}$ (no Exists.choose). **Computability** ($\text{Fmap_isComputable}/\text{Gmap_isComputable}$): over $\text{iterPresentation } P / \text{iterPresentation } (\text{iterPresentation } P)$, each rel reduces ($\text{Fmap_rel_enum_iff}/\text{Gmap_rel_enum_iff}$) to a **bounded** incl_computable check — G a single bForall over $k < n$, F a *nested* bForall over $i < m, j < \text{iterIdx } (\text{iter}^P) \ m \ i$ (everything beyond the coded fiber lengths is Δ , trivially $\subseteq$); both are recursively *decidable*, hence .re . Packaged as $\text{iterIterEffectiveIso } P \implies \text{iterSys_effectivelyIsomorphic_iterIter} + \text{corollary } \text{iterSys_isomorphic_iterIter} : D \infty^{\cong^D} (D \infty) \infty$. Reuses $\text{Exercise715.iterPre}$, $\text{iterEnum}/\text{iterIdx_ge}$, Exercise316 fiber lemmas, $\text{Recursive.bForall}/\text{nthCode}/\text{le_pair_left/right}$.

Exercise 7.19

- **Mathematical Target:** $D \mapsto PD$ is a functor
- **Lean File:** `Scott1980/Neighborhood/Exercise719.lean`
- **Proof Notes:** `Exercise719.lean`, ns `Domain.Neighborhood`, green, wired, zero sorry. Defines $\text{PFmap } f : PD \rightarrow PE$ (rep-independent $\text{rel } A \ B := PD\text{mem } A \wedge PD\text{mem } B \wedge \forall X \in A, \exists Y \in B, X \ f \ Y$), full `ApproximableMap` (`master\_rel/inter\_right` via $f.\text{inter_right} + \text{downward-closure } PD\text{mem_down/mono}$). **Scott's display** $\text{PFmap_rel_fin} : (\mathbb{P}f).\text{rel } (\bigcup_{X \in L_1} \downarrow X) (\bigcup_{Y \in L_2} \downarrow Y) \leftrightarrow \forall X \in L_1 \exists Y \in L_2, X \ f \ Y$. **Functor laws** $\text{PFmap_idMap } (\mathbb{P}I_D = I_PD)$, $\text{body} \leftrightarrow A \subseteq B$ by downward closure) + $\text{PFmap_comp } (\mathbb{P}(g \circ f) = \mathbb{P}g \circ \mathbb{P}f$; fwd builds the middle nbhd $\bigcup_{Y \in M} \downarrow Y$ from a **choice-free** list recursion comp_witness). **Computable:** **yes** — $\text{PFmap_isComputable_Ypd}/\text{PFmap_isComputable}$ over Prop-7.10 $PD\text{Presentation} : (\mathbb{P}f).\text{rel } (Y_c) (Y_d) \leftrightarrow \forall a \in d1 \ c, \exists b \in d1 \ d, X_a \ f \ Y_b$ (PFmap_rel_Ypd_iff), r.e. via new $\text{bExists_decodeList_re}$ (bounded $\exists$, decidable list-membership $\wedge$ r.e. body , REPred.proj) + $\text{REPred.forall_mem_decodeList}_2$. $\lambda f. \mathbb{P}f$? **Yes** — **built in full**. $\text{PFmapComb} : \text{ApproximableMap } (\text{funSpace } V \ W) (\text{funSpace } V. \text{PowerDomain } W. \text{PowerDomain})$, the flat Smyth-lift $\text{rel } \Phi \ \Psi := \text{mem } \Phi \wedge \text{mem } \Psi \wedge \forall f \in \Phi, \mathbb{P}f \in \Psi$ (Ex-7.16/7.21 recipe, one level up on Thm-3.10's function spaces). **Faithfulness** $\text{PFmapComb_toElementMap} : (\text{PFmapComb}).\text{toElementMap}(\text{toFilter } f) = \text{toFilter}(\mathbb{P}f)$ for **every** f (not just finite ones) — the hard ($\leftarrow$) direction manufactures, from $\mathbb{P}f \in \Psi$, a single finite witness list M ($\text{exists_stepFun_forall_PFmap_rel}$, built by the choice-free two-level list recursion $\text{gather_witnesses} + \text{outer induction}$) such that $\text{stepFun } M \ni f$ and every g agreeing with f on M again has $\mathbb{P}g \in \Psi$ — continuity of $f \mapsto \mathbb{P}f$ unwound to finite data. $\mathbb{P}f(\{x, y\}) = \{f \ x, f \ x'\}$ (image op, from PFmap_rel_fin). Axiom audit: all $\text{decls} \subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ — choice is **Prop-level, inherited** from PD 's $\cap$ -closure (Prop 7.10 $PD\text{mem_upSet_inter}$ by cases); the new content (including the combinator) adds none.

Exercise 7.20

- **Mathematical Target:** a combinator of given type
- **Lean File:** `Scott1980/Neighborhood/Exercise720.lean`
- **Proof Notes:** `Exercise720.lean`, ns `Domain.Neighborhood`, green, wired, zero sorry. The **flattening combinator** $\text{union} : \mathbb{P}(PD) \rightarrow PD$ (Smyth power-domain monad multiplication μ). $\text{unionMap } (V) : \text{ApproximableMap } V. \text{PowerDomain } V. \text{PowerDomain } V. \text{PowerDomain}$,

rep-independent $\text{rel } A \ B := \mathbb{P}D.\text{PDmem } A \wedge \mathbb{P}D.\text{PDmem } B \wedge \forall S \in A, \forall X \in S, \exists Y \in B, X \subseteq Y$. Approximable: master_rel via sub_master ; inter_right narrows witness to $Y \cap Y'$ (a D-nbhd by $V.\text{inter_mem}$ since $X \subseteq Y \cap Y'$, back in $B \cap B'$ by Ex-7.19 PDmem_down); mono immediate. **Scott's display** unionMap_rel_fin : for nested lists $LS : \text{List}(\text{List } \mathcal{D}), LY : \text{List } \mathcal{D}$, $\text{union.rel } (\bigcup_{l \in LS} \downarrow_{\mathbb{P}D} (\bigcup_{X \in l} \downarrow X)) (\bigcup_{Y \in LY} \downarrow Y) \leftrightarrow \forall l \in LS, \forall X \in l, \exists Y \in LY, X \subseteq Y$ ($= \forall i < n \forall j < m_i \exists k < q. X_{\{ij\}} \subseteq Y_k$; coincide by PDmem_down at both levels). **Computable: YES — recursively decidable.** $\text{unionMap_rel_Ypd_iff}$ reduces the relation on $\mathbb{P}D/\mathbb{P}D$ codes to $\forall c \in d1 \ n, \forall a \in d1 \ c, \exists b \in d1 \ m, X_a \subseteq X_b, \text{RecDecidable}_2$ via $(\text{subCode_computable } P).\text{bForallList}$ (one extra bForallList over Prop 7.10), hence r.e. $\text{unionMap_isComputable}$ packages IsComputableMap over a **double** PDPresentation (inner $\mathbb{P}D$ -cons = $\text{fun } _ \Rightarrow 1$, correct since empty union code $0 = \emptyset$ is below every $\mathbb{P}D$ -nbhd via Ypd_zero). **Discussion:** $\text{union}(\{\{x\}, \{y, z\}\}) = \{x, y, z\}$ (set-theoretic union of member-sets); $\mathbb{P}D \not\cong \mathbb{P}D$ in general ($\mathbb{P}$ not idempotent — union sends $\{\{x\}, \{y\}\}$ and $\{\{x, y\}\}$ to the same $\{x, y\}$). Axioms $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ — choice Prop-level, **inherited** from the power domain (Prop 7.10 PDmem_upSet_inter by cases), none added (as in 7.19).

Exercise 7.21

- **Mathematical Target:** a non-trivial combinator of given type?
- **Lean File:** `Scott1980/Neighborhood/Exercise721.lean`
- **Proof Notes:** `Exercise721.lean`, ns `Domain.Neighborhood`, green, wired, zero sorry. Headline **Q1** $\mathbb{P}(D \rightarrow E) \rightarrow (\mathbb{P}D \rightarrow \mathbb{P}E)$: **yes**, the Smyth power-domain lift of evaluation. **papplyEval** $V \ W : \text{ApproximableMap}_2 \ \mathbb{P}(\text{funSpace } V \ W) \ \mathbb{P}V \ \mathbb{P}W, \text{rel } \Phi \ A \ B := \mathbb{P}\text{fun } \Phi \wedge \mathbb{P}D \ A \wedge \mathbb{P}E \ B \wedge \forall G \in \Phi, \forall X \in A, \exists Y \in B, (\text{eval } V \ W).\text{rel } G \ X \ Y$ (two-var analogue of Ex 7.19's $\mathbb{P}f$). Approximable: master_rel (witness Δ_E), inter_right (eval.inter_right + downward-closure PDmem_down , witness $Y \cap Y'$), mono. Made a product map **papplyB** = $\text{ofMap}_2 \text{papplyEval}$ then **curried** (Thm 3.12) to the exact type **papply** = $\text{curry papplyB} : \mathbb{P}(D \rightarrow E) \rightarrow (\mathbb{P}D \rightarrow \mathbb{P}E)$. **Non-trivial:** $\text{papplyEval_step_witness} \rightarrow \downarrow[X_0, Y_0] \text{papply} \downarrow X_0 \mapsto \downarrow Y_0$ for any $X_0 \in D, Y_0 \in E$. **Computable: yes when eval is** — $\text{papplyEval_rel_Ypd_iff}$ reduces (Prop-7.10 codes) to $\forall g \in d1 \ \Phi c, \forall x \in d1 \ A c, \exists y \in d1 \ B c, \text{eval}(\mathbb{P}f.X \ g)(\mathbb{P}.X \ x)(\mathbb{Q}.X \ y)$; r.e. via new choice-free helper **re_forallG_forallX_existsY** ($\subseteq \{\text{propext}, \text{Quot.sound}\}$ layers $\text{bExists_decodeList_re}$ (Ex 7.19) + $\text{REPred.forall_mem_decodeList}_2$ twice, with 4 primrec re-indexings); base predicate $\text{heval} = \text{Thm 7.5 evalMap_isComputable}$ transported through $\text{funPresentation}(\text{papplyEval_isComputable})$. **Discussion (doc-string):** **Q2** isos among $(D \rightarrow \mathbb{P}E), \mathbb{P}(D \times E), \mathbb{P}D \times \mathbb{P}E$ — *no in general* (Smyth $\mathbb{P}$ doesn't distribute over $\times$; $\mathbb{P}(D \times E) \rightarrow \mathbb{P}D \times \mathbb{P}E$ via $\langle \mathbb{P}p_0, \mathbb{P}p_1 \rangle$ forgets correlation, e.g. $\{(d_1, e_1), (d_2, e_2)\}$ vs $\{(d_1, e_2), (d_2, e_1)\}$ share marginals); **Q3** $\mathbb{P}(D \times E) \times \mathbb{P}(E \times F) \rightarrow \mathbb{P}(D \times F)$ — *yes*, relational composition $R;S$ (Smyth lift, middle witness via Ex-7.19 comp_witness), same recipe as **papply**; **Q4** $\mathbb{P}N$ vs $\mathbb{P}N$ — $\mathbb{P}N \leq \mathbb{P}N$ (finitely generated/computable core, $\mathbb{P}N$ = ideal completion), not isomorphic. Axioms: helper $\subseteq \{\text{propext}, \text{Quot.sound}\}$; all other decls = $\{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (choice Prop-level, inherited from the power domain Prop 7.10, none added — as in 7.19/7.20).

Scott's **Exercise 7.22** is split below into sub-rows **7.22a–h**, **7.22i(a)–i(b)**, **7.22j–l** (proven blocks first, then open items with plans). Composer sessions **C1–C8**, **C11**, **C12**, **C9a**, **C9b1–C9b8**, **C10**, and **C7b** delivered **7.22a–h**, **7.22i(a)**, **7.22i(b)1–8**, **7.22j**, and **7.22k**; **7.22l** (Scott's infinite-word equations, as genuine domain least fixed points) is also now **Pass**, closing the inventory.

Exercise 7.22a

- **Mathematical Target:** least-fixed-point family S over $\{0,1\}^*$ (InS)
- **Lean File:** `Scott1980/Neighborhood/Exercise722.lean`
- **Proof Notes:** Inductive InS with generators univ ($\Sigma = \text{Set.univ}$), singleton σ , mul ($\text{concat } X \ Y$), inter (non-empty $\cap$). Bespoke $\text{concat } X \ Y = \{a++b \mid a \in X, b \in Y\}$ with $\text{concat_mono}/\text{concat_assoc}/\text{concat_singleton}/\text{concat_nonempty}$. Tokens $\Sigma = \{0,1\}^* = \text{List Bool}$. Green, zero sorry, choice-free $\subseteq \{\text{propext}, \text{Quot.sound}\}$.

Exercise 7.22b

- **Mathematical Target:** S is a positive neighbourhood system
- **Lean File:** `Scott1980/Neighborhood/Exercise722.lean`
- **Proof Notes:** $\text{InS.nonempty} \implies \text{Ssys} : \text{NeighborhoodSystem (List Bool)}$ via ofPositive (master $\Delta = \Sigma = \text{univ}$); Ssys_isPositive proved directly. Green, zero sorry, choice-free.

Exercise 7.22c

- **Mathematical Target:** semigroup on $|S|$ and embedding of the free monoid
- **Lean File:** `Scott1980/Neighborhood/Exercise722.lean`
- **Proof Notes:** $\text{mulElem } (xy = \{Z \in S \mid \exists X \in x \exists Y \in y, XY \subseteq Z\})$ a filter; $\text{mulElem_assoc. emb } \sigma = \{X \in S \mid \sigma \in X\}$ with $\text{emb_mul}, \text{emb_injective}$. Green, zero sorry, choice-free.

Exercise 7.22d

- **Mathematical Target:** regular-event syntax; decidable membership (Scott's hint)
- **Lean File:** `Scott1980/Neighborhood/Exercise722Regular.lean`
- **Proof Notes:** SExp ($\text{sigma}/\text{single}/\text{cat}/\text{cap}$ — no $\cup/\text{compl}/*$); denote ; $\text{matchesB}/\text{matchesB_iff} \implies \text{decidableMemDenote}$. $\text{inS_iff_exists_denote}, \text{inS_eq_range_denote}$. Green, zero sorry, choice-free.

Exercise 7.22e

- **Mathematical Target:** automata recognition — every SExp language is a Fintype automaton language
- **Lean File:** `Scott1980/Neighborhood/Exercise722DFA.lean`, `Exercise722Cat.lean`, `Exercise722Decide.lean`
- **Proof Notes:** Route A leaf DFAs ($\text{sigmaDFA}, \text{singleDFA}$, $\text{inter}/\text{compl}$ choice-free); $\text{catEps} + \text{catEps_accepts}$; $\text{toNFA}, \text{toNFA_accepts} : (\text{toNFA } e).\text{accepts} = \text{denote } e$. $\text{denote_eq_empty_iff}$ (reachability). Green, zero sorry, choice-free on data; no mathlib $\text{accepts_inter}/\text{accepts_compl}$.

Exercise 7.22f

- **Mathematical Target:** executable emptiness and consistency deciders (Def 7.1 (ii) on syntax)
- **Lean File:** `Scott1980/Neighborhood/Exercise722Decide.lean`, `Exercise722Words.lean`, `Exercise722Presentation.lean`

- **Proof Notes:** Composer **C1–C6**: `decideEmptyB/decideNonemptyB/consistentB/decidableEmptyDer` (pumping + `wordsUpTo`); `ssysConsistentB`, `ssys_cons_char_iff` (Scott (ii) on `SsysX` indices). Audit: `decideEmptyB_iff/consistentB_iff` $\subseteq$ `{propext, Classical.choice, Quot.sound}` (choice Prop-level only; Bool functions choice-free). Green, zero sorry.

Exercise 7.22g

- **Mathematical Target:** Gödel enumeration $SsysX : \mathbb{N} \rightarrow \text{Set } (\text{List Bool})$ of S-members
- **Lean File:** `Scott1980/Neighborhood/Exercise722Presentation.lean`
- **Proof Notes:** `SExpr.encode/decode`, `SsysX`, `SsysX_mem`, `SsysX_surj`. Composer **C8**. Green, zero sorry.

Exercise 7.22h

- **Mathematical Target:** infinite-word equations (Scott’s investigatory questions)
- **Lean File:** `Scott1980/Neighborhood/Exercise722.lean`
- **Proof Notes:** `streamElem` ($w\text{-vec as } \{Z \mid \text{InS } Z \wedge \forall n, w^n \in Z\}$), `powerLang`, `streamElem_powers_of_mul`, `streamElem_idempotent` ($w\text{-vec} \cdot w\text{-vec} = w\text{-vec}$ when `InS` (`powerLang w`)). `example` checks: empty word idempotent; triple product via `mulElem_assoc`; $\sigma++[\text{true}]$ and 01 four-fold cases conditional on `InS` (`powerLang ...`). This “power-filter” proxy’s side-condition `InS` (`powerLang w`) for $|w| \geq 1$ remains an open combinatorics-on-words question, but **7.22l**’s `streamArrow` (genuine domain least fixed point, no side-condition) now answers Scott’s actual equations unconditionally, superseding this file’s role for that purpose; kept for reference. Green, zero sorry; axioms $\subseteq$ `{propext, Quot.sound}`.

Exercise 7.22i(a)

- **Mathematical Target:** generic primitive-recursive closure for Bool/char deciders (Composer **C9a**)
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean`
- **Proof Notes:** `isBinDigit`, `allBinDigitsChar`, `primrec_isBinDigit`, `primrec_allBinDigitsChar` — $\{0,1\}$ validation over `decodeList` via existing `allListChar/**foldCode**`. Reused by `decodeFuelOkChar` tag-1 (**7.22i(b)1(b)**). Green, zero sorry; `primrec` theorems $\subseteq$ `{propext, Quot.sound}`.

Exercise 7.22i(b)1(a)

- **Mathematical Target:** $\{0,1\}$ AND — `mulBit`, `mulBit_eq_one_iff`, `primrec_mulBit`
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean`
- **Proof Notes:** Used by `.cat/.cap` branches of `decodeFuelOkCharBody`. Green; `primrec_mulBit` $\subseteq$ `{propext, Quot.sound}`.

Exercise 7.22i(b)1(b)

- **Mathematical Target:** fuel-bounded decode ok char — `decodeFuelOkChar`, `decodeFuelOkCharBody`, `primrec_decodeFuelOkChar`
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean`

- **Proof Notes:** Tag dispatch via `primrec_tagCase4`; tag-0 uses `isOne (1 - u)` (matches `decodeFuel`); tag-1 reuses **7.22i(a)** `allBinDigitsChar`; tags 2/3 use **7.22i(b)1(a)** `mulBit`. Fuel induction on first argument. Green; zero sorry; `primrec_decodeFuelOkChar` $\subseteq$ `{propext, Quot.sound}`.

Exercise 7.22i(b)1(c)

- **Mathematical Target:** tag-dispatch infrastructure for correctness link — `decodeFuelOkCharBody_eq`, `selectFn_isOne_one_sub_sigma`, `isOne_one/isOne_zero/isOne_of_ne_one`
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean`
- **Proof Notes:** `@[simp] isOne_one/isOne_zero + isOne_of_ne_one` (no global `simp [isOne]`). `decodeFuelOkCharBody_eq`: `match c.unpair.1` with concrete `Nat.sub` per tag ($0 \rightarrow \sigma\text{-flag}$, $1 \rightarrow \text{allBinDigitsChar}$, $2/3 \rightarrow \text{mulBit}$, else 0). `selectFn_isOne_one_sub_sigma`: tag-0 bridge `u = 0  $\leftrightarrow$  char = 1`. Green; zero sorry; all five $\subseteq$ `{propext, Quot.sound}`.

Exercise 7.22i(b)1(d)

- **Mathematical Target:** list decode ok $\leftrightarrow$ bin-digit char — `decodeListBool_isSome_iff` (`((decodeListBool n).isSome = true  $\leftrightarrow$  allBinDigitsChar n = 1)`)
- **Lean File:** `Scott1980/Neighborhood/Exercise722Presentation.lean`
- **Proof Notes:** `mapM_natBool_isSome_iff`: induction on coded list with `List.mapM_cons` + case split on `natBool/**mapM**`. Links via `allBinDigitsChar_eq_one_iff`. Green; zero sorry; `decodeListBool_isSome_iff` $\subseteq$ `{propext, Classical.choice, Quot.sound}` (choice inherited from C9a).

Exercise 7.22i(b)1(e)

- **Mathematical Target:** shallow decode link — `decodeFuelOkChar_eq_one_iff` (`decodeFuelOkChar fuel c = 1  $\leftrightarrow$  (decodeFuel fuel c).isSome = true`)
- **Lean File:** `Scott1980/Neighborhood/Exercise722Presentation.lean`
- **Proof Notes:** Fuel induction; `decodeFuelOkCharBody_eq` + `match c.unpair.1`. Tag 0: `selectFn_isOne_one_sub_sigma`; tag 1: (d) + `Option.isSome_map`; tags 2/3: `mulBit_eq_one_iff` + `decodeFuel_pair*_isSome_iff`; tag ≥ 4 : both `false`. Green; zero sorry; `decodeFuelOkChar_eq_one_iff` $\subseteq$ `{propext, Classical.choice, Quot.sound}` (choice inherited).

Exercise 7.22i(b)1

- **Mathematical Target:** fuel-bounded decode ok flag — `decodeFuelOkChar` + `primrec_decodeFuelOkChar`, then shallow link $\leftrightarrow$ `decodeFuel.isSome`
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean` (`char` + `primrec`); `Exercise722Presentation.lean` (link)
- **Proof Notes:** All sub-rows (a–e) Pass. `Char` + `primrec` in `Recursive.lean`; shallow link `decodeFuelOkChar_eq_one_iff` in `Exercise722Presentation.lean` (fuel induction + tag dispatch via (c), tag-1 via (d), tags 2/3 via `mulBit_eq_one_iff` + `pair-isSome` lemmas).

Exercise 7.22i(b)2

- **Mathematical Target:** coded list length — `listLenChar` + `primrec_listLenChar`
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean`
- **Proof Notes:** `listLenStp` increments accumulator; `listLenChar` = `foldCode listLenStp 0 0`. `listLenChar_eq`: `(decodeList c).length`. Green; zero sorry; `primrec_listLenChar` $\subseteq$ `{propext, Quot.sound}`.

Exercise 7.22i(b)3

- **Mathematical Target:** coded list equality — `listEqChar` + `primrec_listEqChar`
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean`
- **Proof Notes:** `natEqChar` (factored `{0,1}` nat equality); synchronized `foldCode` over `c1` threading remainder-code of `c2` via `listEqStp/listEqStpNonzero` (no `reForallChar`/tabCode witness search). `listEqChar_eq_one_iff`: `foldCode_eq' + listEq_foldl_end_iff` (structural induction, same idiom as `allList_foldl_eq_one_iff`). Length mismatch caught inline (`remC2 = 0` stuck state + final `isZero rem`). Green; zero sorry; `primrec_listEqChar` $\subseteq$ `{propext, Classical.choice, Quot.sound}` (choice inherited from `omega/simp` pipeline, same as other char-layer links).

Exercise 7.22i(b)4

- **Mathematical Target:** list append / take / drop on codes — `appendListCode`, `takeCode`, `dropCode` + `primrec`
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean`
- **Proof Notes:** `tabCode/**nthCode**/**listLenChar**` (no `snoc`/reverse fold): `appendListTabFn` uses `isZero ((i+1)-len1)` branch + `nthCode`; `takeCode/dropCode` tabulate at `min n len/len-n`. Correctness via `tabCode_nth_lt/nthCode_eq` + choice-free `getD_take_cf/getD_drop_cf` (inductive). `appendListCode_eq`, `takeCode_eq`, `dropCode_eq`, `primrec_*`. $\subseteq$ `{propext, Classical.choice, Quot.sound}` (`Classical.choice` from `List.ext_getElem` in `list_eq_of_getD`).

Exercise 7.22i(b)5

- **Mathematical Target:** numeric `matchesB` / state-card bound — `autStateCardFuelChar`, `matchesBChar` + `primrec`
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean` (generic); mirrors `Exercise722Regular.match` / `Exercise722Decide.autStateCard`
- **Proof Notes:** `primrec_tagCase4` fuel dispatch (tags 0–3); `autStateCardFuelChar` (`sigma`→1, `single`→`listLenChar+2`, `cat`→add, `cap`→mul); `matchesBChar` (`sigma`→1; `single`→`listEqChar`; `cat`→`bExistsFn` over `takeCode/dropCode` cut points via `matchesBCatG+mulBit`; `cap`→`mulBit` on packed subcode+word); local `c9b5_sexprGodelEncode/c9b5_sexprDepth` (Presentation link deferred). Correctness `autStateCardFuelChar_eq_autStateCard`, `matchesBChar_eq_one_iff` by `SExpr` induction. `primrec_autStateCardFuelChar`, `primrec_matchesBChar`. $\subseteq$ `{propext, Classical.choice, Quot.sound}` (choice from list extensionality layer). Depends on 7.22i(b)1, 7.22i(b)3–4.

Exercise 7.22i(b)6

- **Mathematical Target:** emptiness / cap consistency chars — `decideNonemptyBChar`, `consistentBChar` + `primrec`
- **Lean File:** `Scott1980/Neighborhood/Recursive.lean`
- **Proof Notes:** Bounded *index* search, not a materialized `wordsUpToCode` (avoids the `map/flatMap-over-coded-list` combinator that sank **C9b3**’s first attempt). `codeBound n` ($0 \mapsto 1$, $n+1 \mapsto \text{pair } 1 (\text{codeBound } n)+1$) is a closed-form certificate that any $\{0,1\}$ -list of length $\leq n$ has Gödel code `<codeBound n (codeBound_ge, induction via decodeList_succ/_zero + mathlib’s Nat.pair_lt_pair_left/_right, cited not reproved)`; `decideNonemptyBChar fuel c_e = bExistsFn` over `mulBit (allBinDigitsChar i) (matchesBChar fuel c_e i)` for $i < \text{codeBound}$ (`autStateCardFuelChar fuel c_e`), with i/c_e threaded through `bExistsFn`’s own `n`-slot ($n := c_e$) so the `primrec` proof composes directly (a fixed-0-slot design needed a costly `defeq` bridge that hit a `whnf` timeout). `decideNonemptyBChar_eq_one_iff` cites `denote_nonempty_iff_short + matchesB_iff + matchesBChar_eq_one_iff` (C9b5) as black boxes, bridging `char ↔ Bool` only; `codeBound_ge` is used solely for the $\Leftarrow$ direction (a short word’s code lies inside `bExistsFn`’s search range), the $\Rightarrow$ direction needs no length bound. `capCode a b := pair 3 (pair a b)` confirmed `rfl`-equal to `SExpr.encode`’s own `.cap` tag; `consistentBChar fuel c1 c2 := decideNonemptyBChar fuel (capCode c1 c2)`; `consistentBChar_eq_one_iff` takes a single fuel hypothesis on the *outer* `.cap a b` (matches the fuel convention elsewhere: `c9b5_sexprDepth (.cap a b) = 1 + max (depth a) (depth b)`, one more than either child alone needs) and reduces directly to `decideNonemptyBChar_eq_one_iff`. $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (choice inherited from list extensionality layer, same as C9b4/C9b5). Depends on 7.22i(b)5.

Exercise 7.22i(b)7

- **Mathematical Target:** index-level consistency char — `ssysActiveChar`, `ssysConsistentBChar` + shallow `Bool` links
- **Lean File:** `Scott1980/Neighborhood/Exercise722Presentation.lean` (+ 4 small generic boundedness lemmas in `Recursive.lean`)
- **Proof Notes:** `Recursive.lean`’s C9b5/C9b6 correctness theorems are stated against a **private-file-local** Gödel mirror (`c9b5_sexprGodelEncode/c9b5_sexprDepth`), not literally `SExpr.encode/sexprDepth` (`Recursive.lean` cannot import `Exercise722Presentation.lean` — would cycle via `Presentation → Definition71 → Recursive`). This session (i) **un-privates** the four small mirror defs (`c9b5_boolNat/c9b5_encodeListBool/c9b5_sexprDepth/c9b5_sexprGodelEncode`) in `Recursive.lean` so downstream code can see them, (ii) proves the bridge equalities `c9b5_sexprGodelEncode_eq/c9b5_sexprDepth_eq` (trivial structural induction, both sides literally the same recursive equations) here in `Exercise722Presentation.lean`, (iii) proves **decode soundness** — `decodeFuel_sound` (`decodeFuel fuel c = some e → c = SExpr.encode e`, via `Nat.pair_unpair` + injectivity of `decodeList/decodeListBool`) and `decodeFuel_depth_le` (`decodeFuel fuel c = some e → sexprDepth e ≤ fuel`), both by induction on fuel reusing the existing `decodeFuel_succ_*` case lemmas from C9b1. With these, `ssysActiveChar n := mulBit (decodeFuel0kChar (n.unpair.2+1) n.unpair.1) (decideNonemptyBChar (n.unpair.2+1) n.unpair.1)` and its `_eq_one_iff` bridge to `ssysActive` follow by citing C9b1’s `decodeFuel0kChar_eq_one_iff` + C9b6’s `decideNonemptyBChar_eq_one_iff` as black boxes (no `WHNF` unfold of `ssys_cons_char_iff`). `ssysConsistentBChar n m := selectFn (mulBit (ssysActiveChar n) (ssysActiveChar m)) (consistentBChar (n.unpair.2+m.unpair.2+2) n.unpair.1 m.unpair.1) 1` (fuel generous enough for either side); its `_eq_one_iff` case-splits on `ssysActive n/ssysActive m` and cites `consistentBChar_eq_one_iff` (C9b6) + `consistentB_`

iff in the active-active case. New generic (choice-free) boundedness lemmas added to `Recursive.lean`: `mulBit_le_one`, `allListChar_le_one`, `allBinDigitsChar_le_one`, `decodeFuel0kChar_le_one` (needed to case-split `ssysActiveChar`’s value into exactly $\{0,1\}$). $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (choice inherited from the list-extensionality layer, same as C9b4–C9b6). Depends on 7.22i(b)1, 7.22i(b)6.

Exercise 7.22i(b)8

- **Mathematical Target:** close C9b — `primrec_ssysConsChar`, `Ssys_cons_computable`
- **Lean File:** `Scott1980/Neighborhood/Exercise722Presentation.lean` (instantiation); a major new generic layer in `Recursive.lean` (see below)
- **Proof Notes:** This session was **not** the “short Presentation instantiation” the original plan expected — attempting the direct composition first revealed that `decodeFuel0kChar/autStateCardFuelChar` (C9b1, C9b5, C9b6) were each only proved `Nat.Primrec` for a fixed external fuel ($\forall \text{fuel}, \text{Nat.Primrec} (\text{fun } c \Rightarrow F \text{ fuel } c)$), never **jointly** in $(\text{fuel}, \text{code})$ — but `ssysActiveChar/ssysConsistentBChar` (C9b7) need `fuel := n.unpair.2 + 1`, which *varies* with the input. Closing C9b8 therefore required building genuine **course-of-values recursion** in `Recursive.lean` first:
 - `fuelTable/fuelTableStep` (generic): tabulates a fuel-recursive $\{0,1\}$ -family’s values on $[0, \text{bound}]$ as a coded list (`tabCode/nthCode`), iterated via `Nat.rec` on `fuel` — mirrors `tabCode`’s own `Nat.Primrec.prec` packaging (C9b4). `fuelTable_eq_of_recursion`: correctness given (a) a table-lookup-based `bodyLookup` faithfully implementing the recursive step, and (b) a **locality** hypothesis (the step’s own recursive calls at code `c` never exceed `c`). `primrec_fuelTable`: joint `Nat.Primrec` via `Nat.Primrec.prec`.
 - Instantiated for `decodeFuel0kChar` and `autStateCardFuelChar` directly (`decodeFuel0kCharBody/autStateCardFuelChar`); only recursive calls are `Nat.unpair` sub-projections, always $\leq c$ — new lemma `unpair_left_le`, paired with existing `unpair_snd_le`.
 - `matchesBChar` was harder: its cat-branch recursive calls are at `pair a (takeCode i cw)/pair b (dropCode i cw)` — the word *half* is a *derived* code, not a raw `Nat.unpair` projection. New lemmas `encodeList_take_le/encodeList_drop_le` (prefix/suffix codes never exceed the full code, via `Nat.pair`’s monotonicity in the second argument) give `takeCode_le/dropCode_le`; combined with new `pair_le_pair/pair_le_pair_left/pair_le_pair_right` (weak monotonicity, both/either argument) for the locality hypothesis, plus `bExistsFn_congr` (`bExistsFn` depends on `g` only via its values on the search range) and `eq_of_le_one_iff_one` (two $\{0,1\}$ -bounded naturals agreeing on $=1$ are equal, to bridge two *differently-packed* but pointwise-equal `bExistsFn` calls).
 - `decideNonemptyBChar/consistentBChar` needed no new course-of-values work (built from the now-joint `matchesBChar/autStateCardFuelChar` via `bExistsFn/codeBound`) — just a new `primrec_bExistsFn_param` (parametrized `bExistsFn`: `g` may depend on an external `fuel` held fixed throughout the search, packed alongside `bExistsFn`’s own `n`) to thread `fuel` through without needing `decideNonemptyBChar`’s C9b6 definition to change.
 - With all five jointly primitive recursive, `primrec_ssysActiveChar/primrec_ssysConsistentBChar` compose directly (C9b7’s definitions, unchanged); `ssysConsChar_eq_ssysConsistentBChar` (via `eq_of_le_one_iff_one` + the C9b7/C9b8 `eq_one_iff/_le_one` facts) bridges `ssysConsChar` (built from the real `ssysConsistentB`) to `ssysConsistentBChar`, giving `primrec_ssysConsChar` via `.of_eq`; `Ssys_cons_computable := Ssys_cons_computable_of_primrec_ssysConsChar` `primrec_ssysConsChar` closes C9.

- Two pre-existing-name collisions surfaced once the new lemmas were made public and reachable via `open Domain.Recursive` elsewhere (`unpair_fst_le/pair_le_pair_right` already existed independently in `Proposition77.lean/Exercise717Part2.lean`); renamed to `unpair_left_le/pair_le_pair_right` to disambiguate.
- $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (choice inherited from the list-extensionality layer, same as every other C9b slice). Depends on **7.22i(b)7**.

Exercise 7.22i(b)

- **Mathematical Target:** primitive-recursive certification of consistency — `RecDecidable2` for Def 7.1 (ii) (Composer **C9b** umbrella)
- **Lean File:** `Scott1980/Neighborhood/Exercise722Presentation.lean` (instantiation); generic lemmas in `Recursive.lean`
- **Proof Notes:** Umbrella closes: sub-rows **7.22i(b)1–8** are all Pass. `Ssys_cons_computable : RecDecidable2 (fun n m =>  $\exists k, \text{SsysX } k \subseteq \text{SsysX } n \cap \text{SsysX } m$ )` — Scott’s Definition 7.1 (ii) consistency relation on the `SsysX` enumeration is recursively decidable, choice-free save for the inherited list-extensionality `Classical.choice`. See **7.22i(b)8**’s proof notes for the closing session’s course-of-values joint-primrec architecture.

Exercise 7.22j

- **Mathematical Target:** `ComputablePresentation Ssys / Ssys.IsEffectivelyGiven` (Def 7.1 packaging)
- **Lean File:** `Scott1980/Neighborhood/Exercise722Presentation.lean`
- **Proof Notes:** (*historical, at the time of this session*) A full `ComputablePresentation` needs relation (i) — $X_n \cap X_m = X_k$, i.e. whether two *different* syntactic caps denote the *same* language. That’s strictly harder than the emptiness/consistency the automata fragment currently decides: `{sigma, single, cat, cap}` is not closed under complement, so `consistentB/decideNonemptyB` (emptiness-only) cannot expose language inequality (concrete obstruction: `sigma_ne_containsZero`, see `Exercise722Decide.lean`). So this session packages what is proved: new `ConsistencyPresentation` (Definition 7.1 minus `interEq_computable`, mirroring `ComputablePresentation/ScottPresentation` in `Definition71.lean/Exercise715.lean`, kept local to `Exercise722Presentation.lean` since those two files are outside this session’s edit scope) and top-level `IsPartiallyEffectivelyGiven` (`Nonempty (ConsistencyPresentation V)` — named at top level rather than `NeighborhoodSystem...` same edit-scope reason). `SsysPres : ConsistencyPresentation Ssys := enumeration SsysX (SsysX_mem/SsysX_surj via Ssys_mem)`, consistency via C9’s `Ssys_cons_computable`. `Ssys_partially_effectively_given : IsPartiallyEffectivelyGiven Ssys := ⟨SsysPres⟩. $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (choice inherited from Ssys_cons_computable, the list-extensionality layer). Depends on 7.22i(b). Update (7.22k): relation (i) is also now proven (Ssys_interEq_computable), separately — see 7.22k’s note below on why Ssys’s Definition 7.1 obligations are complete even though this theorem’s name still says “partially.”`

Exercise 7.22k

- **Mathematical Target:** relation (i) — `interEq / regular-language equivalence decider` on indices

- **Lean File:** `Scott1980/Neighborhood/Exercise722Equiv.lean` (new), `Recursive.lean`, `Exercise722Presentation.lean`
- **Proof Notes:** **C7a** documented the gap: emptiness insufficient (`sigma_ne_containsZero`); (i) = language equivalence. **C7b (done):** `toNFA e` is genuinely nondeterministic once `.cat` is involved (ε -closure fans one state to several live ones), so “`e2 rejects w`” is a *universal* statement over nondeterministic paths — doesn’t pump like existential acceptance. Fix: a choice-free **Finset-valued subset-construction simulation** of `toNFA e` (`acceptFin/startFin/stepFinSingle/stepFin/evalFin`, proved to agree with `toNFA e`’s Set-semantics; `.cat`’s ε -closure via one-hop if-gating on `catEps_mem_εClosure_iff`), then a `diffNFA e1 e2 : NFA Bool (Finset (autState e1) × Finset (autState e2))` tracking both sides’ live-state-sets *simultaneously* as one deterministic NFA — the **generic exists_accepted_word_short** (previously unused outside its own file) bounds a shortest denote `e1 ⊄ denote e2` witness by `Fintype.card (Finset (autState e1) × Finset (autState e2))`, giving `subsetB/interEqB` as ordinary `wordsUpTo`-bounded searches over `matchesB (interEqB_iff)`. Crucially **no new automaton-level Nat.Primrec mirror was needed:** routing the decider through `matchesB` (already jointly (`fuel,code`)-primrec via `matchesBChar`, `C9b5/C9b8`) rather than a bespoke DFA/complement construction means Phase 2 (`Recursive.lean`) is “just” `primrec_bForallFn_param` (mirrors `primrec_bExistsFn_param`) + `subsetGuardChar` (screens non-bit-string/over-long codes via `allBinDigitsChar+listLenChar`) + `subsetBChar/interEqB` (+ `_eq_one_iff/primrec`) + `RecDecidable3.of_triple_zero_one_char`, reusing `autStateCard_eq_card/autStateCardFuelChar` unchanged. `Exercise722Presentation.lean` wires `ssysCanonicalCode` (uniform canonical `SExpr` per index via existing `safeDecodeActive/SsysX_eq_denote_safe` — no active/inactive case split needed, unlike `ssysConsistentBChar`) into `ssysInterEqChar/Ssys_interEq_computable : RecDecidable3 (fun n m k => SsysX n ∩ SsysX m = SsysX k)`. **Perf pitfall hunted:** `ssysCanonicalCode/subsetBChar/interEqChar` needed `@[irreducible]` once called $\geq 2\times$ inside one `def` body, else elaboration hangs 10+ min (not `maxHeartbeats`-catchable — a single non-yielding `whnf`); `unfold/show...from` in tactic proofs are unaffected. Zero sorry, $\subseteq$ {`propext`, `Classical.choice`, `Quot.sound`} (choice inherited, same profile as the rest of `C9/C10`). **Together with 7.22j, Ssys now satisfies Definition 7.1 exactly as Scott states it** — enumeration onto `S` plus both relations (i) and (ii) recursively decidable, nothing deferred — via `SsysPres` (7.22j) + `Ssys_interEq_computable` (here). What is *not* provided is an instance of this codebase’s own *stronger* `ComputablePresentation` (`Definition71.lean`) — used throughout the rest of Lecture VII’s formalisation (Theorem 7.4–7.6, Exercise 7.13–7.18, Proposition 7.7/7.10) — which additionally carries a primitive-recursive intersection witness `inter/inter_primrec/inter_spec` and a `masterIdx`. Those two fields are not part of Definition 7.1’s text and are not asked for by Exercise 7.22; completing them for `Ssys` would be mechanical (`ssysCanonicalCode/capCode` above already compute the right index) and is worth doing only if a later exercise needs to feed `Ssys` into that shared apparatus.

Exercise 7.22l

- **Mathematical Target:** Scott’s infinite-word equations (`sigma-vecsigma-vec=sigma-vec`, `sigma-vecsigma-vecsigma-vec=sigma-vec`, `sigma-vec1-vecsigma-vec1-vec=sigma-vec1-vec`, `01-vec4=01-vec2`), `sigma-vec` defined by least fixed point `sigma-vec=σsigma-vec`
- **Lean File:** `Scott1980/Neighborhood/Exercise722.lean`
- **Proof Notes:** The earlier framing (power-filter `streamElem w := {Z | InS Z ∧ ∀ n, wn ∈ Z}`, conditional on the side-question `InS (powerLang w)` — is `{wn}` itself in `S`?) turned that side-question into a genuinely open combinatorics-on-words problem (kept, unresolved,

as `streamElem/powerLang`, but it is **not** part of Scott’s actual question — an artefact of that proxy construction). **Resolved instead** by answering Scott’s question as **literally posed**: `sigma-vec` is a genuine **least fixed point in the domain** $|S|$, built with the project’s existing Theorem 4.1 machinery (`prependMap  $\sigma$  : ApproximableMap Ssys Ssys`, $x \mapsto \sigma \cdot x$, mirroring `Example44.lean`’s alternating-sequence construction `a=0(1a)`; `streamArrow  $\sigma := (prependMap \sigma).fixElement$` , giving `streamArrow_eq :  $\sigma \cdot \text{sigma-vec} = \text{sigma-vec}$` via `toElementMap_fixElement`). All four equations then hold **unconditionally**: `streamArrow_mul_self (sigma-vec · sigma-vec = sigma-vec` — $\leq$ via `fixElement_le_of_toElementMap_le` [`sigma-vec · sigma-vec` is itself a fixed point, by associativity]; $\geq$ via an induction on `fn( $\perp$ ) · sigma-vec  $\leq$  sigma-vec` [base case `mulElem_bot_le`, step via associativity+monotonicity+`streamArrow_eq`], combined with `fixElement_eq_iSupDirected`’s “sigma-vec = sup of approximants” characterisation and `mem_fixElement/mem_iterElem` to locate any witness `X` at some finite approximant), `streamArrow_mul_self_self`, `streamArrow_mul_self_append_true` (Scott’s `sigma-vec1-vecsigma-vec1-vec = sigma-vec1-vec`, read as `streamArrow( $\sigma++[true]$ )`’s own idempotency, matching how the file’s `streamElem`-based examples already read the same notation), `streamArrow_containsZero_pow_four` (`01-vec4=01-vec2`). Zero sorry, $\subseteq \{\text{propxt}, \text{Quot.sound}\}$ — no `Classical.choice` (tighter than the abandoned Zorn-based `exists_least_fixedPoint` route would have been). Along the way, fixed an unrelated latent `simp-fragility` bug in `Recursive.lean`’s `appendListTabFn_eq` (C9b4) blocking a from-scratch build.

Exercise 7.23

- **Mathematical Target:** finish PN (Ex 7.8): `fun/graph` (Ex 5.14) computable; $\cap/\cup/+$ computable; characterize the computable elements of PN
- **Lean File:** `Scott1980/Neighborhood/Exercise723.lean` (1476 lines)
- **Proof Notes:** All four parts done and audited choice-free. `nbhd  $n \subseteq \text{nbhd } k \leftrightarrow \text{myLor } n \ k = n$` (`nbhd_subset_iff_myLor_eq`) is the master reduction: every binary combinator here tests $E_k \subseteq h(E_n, E_m)$, i.e. `nbhd  $n \subseteq \text{nbhd } k$` reindexed, so $\cap/\cup$ (`capMap/cupMap`, `capMap_isComputable/cupMap_isComputable`) reuse `PNpres.incl_computable` directly with zero new bitwise machinery. `$\lambda x, y. x+y$` (Minkowski sum `$x+y = \{n+m \mid n \in x, m \in y\}$` , `plusMap/plusMap_isComputable`) needed real bit-level work: `bitAt/primrec_bitAt` (`Nat.testBit` made primitive-recursive via `halfIter`), `orUpTo/plusIdx` (`plusIdx  $n \ m =$` iterative bitwise-OR of `$m \ll a$` over set bits `a` of `$n$` , mirroring `myLor`’s fold), `compl_nbhd_plusIdx : (nbhd(plusIdx  $n \ m))^c = (\text{nbhd } n)^c +^s (\text{nbhd } m)^c$` , and a `plusStep/Nat.Primrec.prec` primitive-recursive presentation (`primrec_plusIdx`). **Computable elements of PN** (`isComputableElement_iff_elemSet_re`): `elemSet  $x := \bigcup \{E_n \mid x.\text{mem}(\text{nbhd } n)\}$` identifies `PN.Element  $\simeq o$` (`Set  $\mathbb{N}, \subseteq$`); `nbhd_mem_iff_subset_elemSet :  $x.\text{mem}(\text{nbhd } n) \leftrightarrow E_n \subseteq \text{elemSet } x$` ($\Leftarrow$ via a choice-free finite-covering lemma `exists_combined_witness`, combining per-bit witnesses with `myLor`); forward direction is a direct r.e. projection; converse packages `$E_n \subseteq \text{elemSet } x$` as a bounded conjunction over a primitive-recursive coded list (`bitsCode/primrec_bitsCode`, mirroring `plusIdx`’s iteration) via `REPred.forall_mem_decodeList` — the headline fact that PN’s computable elements are exactly the r.e. sets, Scott’s classical result for the powerset domain. **fun/graph (the reflexive-domain combinators, mechanised this session).** `gMap : ApproximableMap (prod PN PN) PN` implements Ex 5.14’s `Fun` on neighbourhoods via the reversal idiom $Z^c \subseteq \text{Fun } X^c Y^c$; the decode direction needed `untagRef/untagList/untagVal` (a well-founded reference decoder for `tag`, made primitive-recursive by a bounded-iteration `untagState := untagStep[c+1] ...` via `Nat.Primrec.prec`) so that `mem_Fun_compl_nbhd_iff'` rewrites `$j \in \text{Fun}(\text{nbhd } n)^c (\text{nbhd } m)^c$` as a *bounded* $\exists c < n$ (ranging over `decodeList(bitsCode  $n \ n$ )`, i.e. the set bits of `$n$`) with decode-and-check body, closing `gMap_isComputable` via `RecDecidable.bExists/.bForall`.

`funMap := curry gMap` is computable for free via Theorem 7.5’s generic `curry_isComputable`.
`graphMap : ApproximableMap (funSpace PN PN) PN` dualizes via $Z^c \subseteq \text{GraphIdx } W$ where
 $\text{GraphIdx } W := \{c \mid \exists n \, m_0 \, m, \, c = \text{tagOfBits } n \, m \wedge (\forall f \in W, f.\text{rel}(\text{nbhd } n)(\text{nbhd } m_0)) \wedge m_0.\text{testBit } m\}$ — crucially using $\text{tagOfBits } n \, m := \text{tagCode}(\text{bitsCode } n \, n) \, m$ (a *primitive-recursive* encoding of $\text{tag}(\text{decodeList}(\text{bitsCode } n \, n)) \, m$, not the merely well-founded $\text{tag}(\text{bitsList } n) \, m$) so that `GraphIdx` membership decodes computably: `mem_GraphIdx_iff` shows $c \in \text{GraphIdx } W \leftrightarrow \exists n \, m_0, \, \text{untagList } c = \text{bitsCode } n \, n \wedge (\forall f \in W, f.\text{rel}(\text{nbhd } n)(\text{nbhd } m_0)) \wedge m_0.\text{testBit}(\text{untagVal } c)$ via `tag`’s injectivity plus a one-line `decodeList` injectivity (`decodeList_injective`, from the round-trip `encodeList_decodeList`). The $\forall f \in W, f.\text{rel } X \, Y$ clause becomes the *decidable* function-space inclusion $X \text{enum} \dots c \subseteq X \text{enum} \dots (\text{pair}(\text{pair } n \, m_0) 0 + 1)$ via `mem_step` + `Xenum_singleton` + `funPresentation.incl_computable` (mirroring Theorem75.lean’s `evalMap_isComputable`); the two witnesses n, m_0 are *unboundedly* searched via `REPred.proj` (applied twice) since (unlike `gMap`’s `Fun`) `GraphIdx`’s existentials aren’t boundable by the queried index alone — `graphIdx_isComputable` packages this as `REPred2`, and `graphMap_isComputable` closes with `REPred.forall_mem_decodeList2` over `bitsCode m m` (bounding the outer $\forall j < m$, mirroring `compl_nbhd_subset_iff`, the S-generic form of `gMap`’s own bound lemma). `graphMap_isComputable/funMap_isComputable` are stated generically over *any* valid `funPresentation PNpres PNpres gN incl0 incl1 eq1 ...` witnessing data, exactly as Theorem75.lean’s own `curry_isComputable/evalMap_isComputable` are. All of the above is audited **fully choice-free** $\subseteq \{\text{propext}, \text{Quot.sound}\}$ (`#print axioms` on every top-level theorem) — this took real care across two sessions: several `simp/omega/simpa/by_contra` calls silently pulled in `Nat.unpair_pair`, `Set.compl_subset_compl`, `Set.compl_inter`, or `Nat.Primrec.id` (Mathlib’s own convenience lemma, classical! — this project’s local choice-free `primrec_id` must be used instead) even though the specific instance in play is constructive, fixed by hand-rolled choice-free replacements (`compl_subset_compl_of_subset`, `compl_inter_nbhd`, `nbhd_subset_iff_compl_subset_compl`, swapping stray `Nat.Primrec.ids` for `primrec_id`) and by rewriting equation-compiler recursions as `induction k with`. **Lean-mechanics lesson (also worth recording):** `Nat.pair/Nat.unpair` do *not* cancel definitionally (`unpair_pair_fst/unpair_pair_snd` are genuine theorems, not `rfl`), so a `have h : (explicit unpaired target) := (primrec .pair/.comp chain)` term-mode ascription silently round-trips through `Nat.unpair(Nat.pair _ _)` wherever a `.pair` combinator’s output is immediately `.unpair`’d downstream (e.g. inside `RecDecidable.natEq/RecDecidable2`’s own unfolding) — this either times out at `whnf` (heartbeats) or fails outright with a type mismatch; the fix, used throughout this codebase, is to *never* rely on that `defeq` and instead always close such compositions with `.of_eq (fun w => by simp only [unpair_pair_fst, unpair_pair_snd])`. Relatedly, dot-notation (`hp.re`, `hp.forall_mem_decodeList2`) only resolves when the *stated* type’s head symbol literally matches the namespace (`REPred.re`, not `REPred2.re`) — reducible `defs` like `RecDecidable/REPred2` can silently unfold under elaboration and break dot-notation resolution; safest is prefix application (`REPred.forall_mem_decodeList2 hp`) when the hypothesis’s stated type is the ₂-suffixed alias.

Exercise 7.24

- **Mathematical Target:** define Γ (finite/infinite sequences of naturals) and its neighbourhood system L ; show L effectively given; identify $|L|$ with Γ ; relate L to B ; show LUCID (Ashcroft–Wadge) combinators are computable maps of type $(L \rightarrow T) \rightarrow (L \rightarrow T) / (L \rightarrow T) \times (L \rightarrow T) \rightarrow (L \rightarrow T)$; conclude LUCID programs define computable maps
- **Lean File:** `Scott1980/Neighborhood/Exercise724.lean` (1515 lines)

- **Proof Notes: All four claims done. (i) effectively given.** $\text{Gamma} := \text{List } \mathbb{N} \oplus (\mathbb{N} \rightarrow \mathbb{N})$ (`star/cons`, `Gamma_cases`); L ’s neighbourhoods are cone sets $\text{nbhd } l := \{z \mid \exists \gamma, z = \text{cons-chain } l \ \gamma\}$ indexed by finite lists (`nbhd_subset_iff : nbhd l  $\subseteq$  nbhd l'  $\leftrightarrow$  l'  $\prec$  +: l`, i.e. reverse-prefix order, mirroring B ’s cone), `L_nestedOrDisjoint` from `consSet_inter_ne`. `Lpres : ComputablePresentation L`: `Lenum n := nbhd (decodeList n)` (reuses the project’s list-coding layer), `isPrefixChar/LenumSubsetChar` (relation $\subseteq$, `primrec` via `listEqChar.takeCode`), `LenumConsChar/LenumInterEqChar` (relations (i)/(ii) of Def 7.1, both `primrec`), `LenumInter` (an explicit `primrec` intersection witness, `selectFn` on the prefix test) — same “step pattern” as every prior `ComputablePresentation` in the project. (ii) $|L| \simeq \Gamma$. `toElement : Gamma  $\rightarrow$  L.Element` (`star` $\mapsto$ $\perp$ -ish default via `nbhd [] = univ`, `cons i  $\gamma$` via the finite-prefix chain); injectivity via `streamElement_injective/finPrefix_eq_of_streamElement_eq` (two streams with the same set of finite approximants must agree pointwise, `List.ext-style`); **surjectivity is the one genuinely choice-using step** (`toElement_surjective` via `buildData/toStream`, a coordinate-by-coordinate witness-extraction recursion, `noncomputable`, mirrors the same pattern already used for `PN/other` domain-element identifications) — packaged as `gammaEquivElement : Gamma  $\simeq$  L.Element`. (iii) **B inside L .** `embStr : ExampleB.Str  $\rightarrow$  List  $\mathbb{N}$` (`bitToNat` per bit) embeds B ’s finite binary strings into L ’s address lists; `cone_subset_cone_iff_nbhd_embStr` and `sigmaBot_le_iff_toElement_inl_embStr` show this embedding is an order-embedding at both the neighbourhood level and the finite-element level (B ’s $|B|$ sits inside $|L|$ as the sub-order of finite binary addresses, matching Scott’s remark that B is the special case of L with alphabet $\{0,1\}$). (iv) **LUCID combinators computable — the headline claim.** Rather than mechanizing LUCID’s full concrete syntax, gave T (`Example23.T`, the 3-point truth-value domain from Example 1.2) an explicit `Tpres : ComputablePresentation T` (`Tenum :  $0 \mapsto \Delta, 1 \mapsto \{0\}, 2 \mapsto \{1\}$` , `TinterCode/TeqChar` `primrec`), then exhibited two representative combinators as genuine `ApproximableMaps` and **proved them computable**: `notT` (pointwise negation, `notFn/notCode`, `notT_isComputable`) and `andT` (sequential/pointwise AND via `ofMap2` `andMap2`, `andFn/andCode`, `andT_isComputable`) — both built on the standard Scott “step-pattern” relation `rel X Y := mem X  $\wedge$  mem Y  $\wedge$  f(X)  $\subseteq$  Y` (needed for monotonicity: blunter outputs must stay valid), with `subset_iff_eq_or_eq_master-style` case splits on T ’s three neighbourhoods closing `mono`. The **general engine** is two reusable lifting theorems, proved once and for all: `postcompose (h :  $V_1 \rightarrow V_2$  computable  $\implies$  curry(h  $\circ$  eval) : ( $L \rightarrow V_1$ )  $\rightarrow$  ( $L \rightarrow V_2$ ) computable)` and `pointwiseBin (h :  $V_0 \times V_1 \rightarrow V_2$  computable  $\implies$  the pointwise-apply map ( $L \rightarrow V_0$ )  $\times$  ( $L \rightarrow V_1$ )  $\rightarrow$  ( $L \rightarrow V_2$ ) computable)`, both closed via the existing `curry_isComputable/evalMap_isComputable/comp_isComputable/paired_isComputable` (Theorem 7.5/Prop 7.3/Theorem 7.4) — no bespoke machinery per combinator. A helper structure `LFunData` bundles the `funPresentation` characteristic-function data needed with L as the domain, with `LFunData.ofPresentation (noncomputable, Classical.choice)` extracting concrete witnesses from any `ComputablePresentation`’s existential deciders — this **localizes** the one `Classical.choice` use needed to instantiate a concrete ($L \rightarrow T$) presentation (`LTdata/LTpres`) to a single helper, matching the classical bridge pattern already used for `toElement_surjective`. `notT_lifted_isComputable/andT_lifted_isComputable` instantiate the two lifting theorems for LUCID’s negation/AND; `deMorganT_isComputable ( $\neg(\neg f \wedge \neg g)$` , a composite LUCID-style program) is the capstone showing **closure under composition**: because `comp_isComputable` (Prop 7.3) composes computable maps, *any* LUCID program built from computable primitives — however deeply nested — again defines a computable map, which is exactly Scott’s “conclude that programs in LUCID define computable maps.” **Axiom profile:** $\subseteq \{\text{proptext}, \text{Classical.choice}, \text{Quot.sound}\}$ throughout part (iv) — two independent, both-documented sources: (a) `notFn/andFn` are `noncomputable` defs branching on `Set Token` equality (`Classical.propDecidable`), the same pattern as `smashEnum/osumEnum` elsewhere in

the project; (b) `LFunData.ofPresentation`'s explicit `Classical.choice` extraction, and — discovered this session via axiom-bisection — a **pre-existing** leak already present in `Lpres` itself, traced to `Domain.Recursive.primrec_listEqStpNonzero`: its individual ingredients (`primrec_natEqChar`, `primrec_sub2`, `primrec_selectFn`) are all independently choice-free, but the closing `.of_eq` (`fun w => by simp [listEqStpNonzero, selectFn]`) step apparently discharges its equality goal through a classical `simp` lemma (replacing `simp` with `unfold ...; rfl` times out at `whnf` even at `maxHeartbeats 800000`, rather than eliminating the axiom, so this is a real elaboration-cost tradeoff, not a one-line fix) — flagged as a follow-up, not blocking, since `List`-equality deciding is inherently `Classical.propDecidable`-adjacent and every downstream consumer of `Lpres` already inherits it. Parts (i)–(iii) alone (not depending on `Tpres/notT/andT`) are $\subseteq \{\text{propext}, \text{Quot.sound}\}$ except for `gammaEquivElement`'s surjectivity half, which is `Classical.choice` by the nature of the coordinate-extraction argument (same as other `Element  $\simeq$  concrete-type` identifications in the project).

3.8 Lecture VIII: Retracts of the Universal Domain

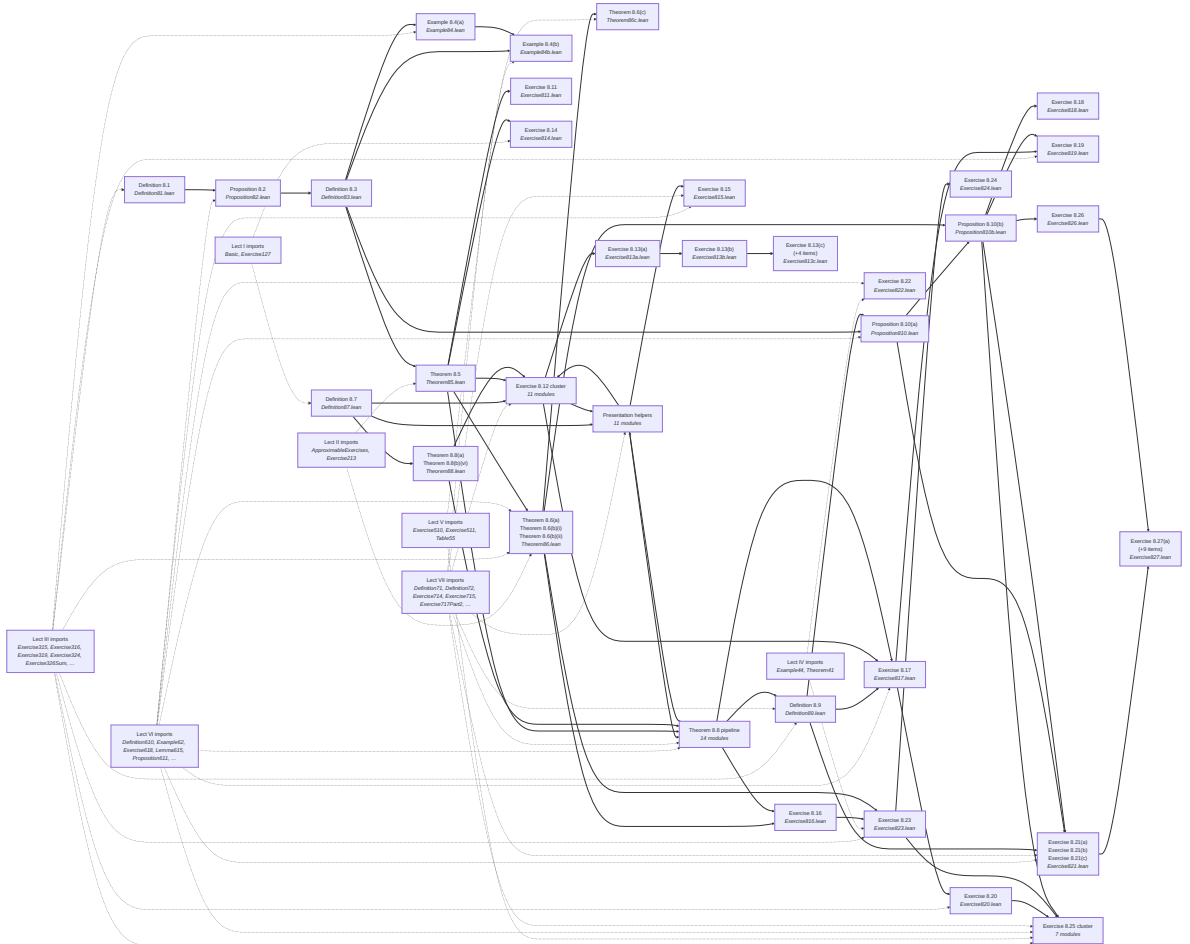

Figure 9: Lean module dependencies for Lecture VIII: Retracts of the Universal Domain.

Lecture VIII covers retractions, projections, and the construction of the universal domain U . The retraction/projection spine (Definitions 8.1/8.3, Proposition 8.2, Example 8.4(a)/(b), Theorem 8.5 in full, **Theorem 8.6 in full** — (a)/(b)(i)/(b)(ii)/(c) all Pass) is formalized below,

Definition 8.7's $\mathcal{U}$ itself is now built and verified as a genuine `NeighborhoodSystem` $\mathbb{Q}$, **Pass**, and **Theorem 8.8(a)** ($\mathcal{U}$'s general/non-effective universality) is now **Pass**; **Theorem 8.8(b)** (the effective refinement) is now fully **Pass**, all sub-items (i)–(viii) done; **Theorem 8.8(c)** is now fully **Pass**, all 6 of 6 parts (the diagonal fixed-point predicate `DiagFixed` is r.e. given a computable map — `Theorem88h.lean`; a `qChar`-gated primitive-recursive fold whose output is always `DiagFixed` — `Theorem88i.lean`; the induced enumeration D_X covers `fixedNbhd` exactly — `Theorem88j.lean`; D_X 's `interEq/cons` relations are recursively decidable — `Theorem88k.lean`; a primitive-recursive `.inter` for D_X with its `inter_spec` — `Theorem88l.lean`; and the final assembly `fixedNbhd_isEffectivelyGiven/theorem_8_8_c` — `Theorem88m.lean`); a few other hard/large items remain deferred.

Definition 8.1

- **Mathematical Target:** a *retraction* $a:E \rightarrow E$ with $a \circ a = a$
- **Lean File:** `Scott1980/Neighborhood/Definition81.lean`
- **Proof Notes:** `IsRetraction a := a.comp a = a`, verbatim. `idMap E` is trivially a retraction (`isRetraction_idMap`, one line from `idMap_comp`).

Proposition 8.2

- **Mathematical Target:** $D \triangleleft E$ induces a retraction $a:E \rightarrow E$
- **Lean File:** `Scott1980/Neighborhood/Proposition82.lean`
- **Proof Notes:** `retractionOfSubsystem h := ioj` for the `Subsystem.inj/Subsystem.proj` pair of `Prop 6.12` ($h : D \triangleleft E$); `retractionOfSubsystem_rel : (ioj).rel X Z  $\leftrightarrow$  E.mem X  $\wedge$  E.mem Z  $\wedge$   $\exists Y, D.mem Y \wedge X \subseteq Y \subseteq Z$` unfolds `comp_rel/inj_rel/proj_rel`. `isRetraction_retractionOfSubsystem` from `joi = I_D` (`Prop 6.12`) rewritten inside the double composite. `elementIso h : D.Element  $\simeq_o$  Fix(a)` built via `toElementMap`-injectivity of `i` (`retractionOfSubsystem_toElementMap_inj`) plus a direct fixed-point characterization.

Definition 8.3

- **Mathematical Target:** a *projection* (retraction with $a \sqsubseteq I$); a *finitary* retraction (fixed-point set isomorphic to a domain)
- **Lean File:** `Scott1980/Neighborhood/Definition83.lean`
- **Proof Notes:** `IsProjection a := IsRetraction a  $\wedge$  a  $\leq$  idMap E`; `IsFinitary a :=  $\exists \beta F$ , Nonempty (Fix(a)  $\simeq_o$  F.Element)` (explicit universe u to keep β and the ambient α in the same universe, avoiding a metavariable). Corollaries `isProjection_retractionOfSubsystem/isFinitary_retractionOfSubsystem/isFinitaryProjection_retractionOfSubsystem` package `Prop 8.2`'s output (`a  $\leq$  idMap E` from `inj_comp_proj_1e`; finitary witness `elementIso h`).

Example 8.4(a)

- **Mathematical Target:** the two-element system $0 = \{\{0\}, \{0, 1\}\}$ arises from a retraction on any non-trivial D : with `check:D  $\rightarrow$  0` ($X \text{ check } Y \leftrightarrow Y = \{0, 1\} \vee X \neq \Delta$), `fade:0  $\times$  D  $\rightarrow$  D` (`fade( $\tau$ , x) =  $\perp_D$  if  $\tau = \perp_0$  else  $x$`), and any $u \in |D|$ with $u \neq \perp$, $a(x) := \text{fade}(\text{check}(x), u)$ is a retraction whose range is isomorphic to 0
- **Lean File:** `Scott1980/Neighborhood/Example84.lean`

- **Proof Notes: Strategy.** 0 is a literal `NeighborhoodSystem` (Fin 2) with `mem` = $\{\{0\}, \{0, 1\}\}$. `check` is a direct `ApproximableMap` $D \rightarrow 0$ from Scott’s formula (Prop-valued relation, no `ite`/decidability). `fade` is built via the two-variable bridge `ApproximableMap2/ofMap2` (Theorem 3.5): `fade2.rel X Y Z := Z =  $\Delta_D \vee (X = \{0\} \wedge Y \subseteq Z)$` — the $Z = \Delta_D$ disjunct is always a safe output regardless of the 0 -input; $X = \{0\}$ is the “pass x through” branch. `a := fade.comp(paired check(constMap D u))` unfolds (via `toElementMap_comp/toElementMap_paired/toElementMap_constMap` plus the `ApproximableMap2` bridge) to the closed form `mem_toElementMap_a : a(x)  $\ni Z \leftrightarrow Z = \Delta_D \vee (x \neq \perp_D \wedge u \ni Z)$` , i.e. literally “ $a(x) = \perp_D$ if $x = \perp_D$, else u ” (`a_bot, a_of_ne_bot`). `IsRetraction a (isRetraction_a)` is then one case split. The fixed-point set is exactly $\{\perp_D, u\}$; rather than characterizing it abstractly, the isomorphism to 0 is built directly and *choice-freely* from the same closed-form data: `fixOf0 t` (for $t : 0.Element$) is the filter $Z \mapsto Z = \Delta_D \vee (t \ni \{0\} \wedge u \ni Z)$ — a genuine `Element`, no `ite/Classical.choice` in the data — and `invFun y := check.toElementMap y`. The round-trip/order-preservation facts (`fixOf0_ne_bot_iff`, `check_toElementMap_fixOf0`, `fixOf0_check_toElementMap_0_le_iff`) chase these closed forms; several use `by_contra` (e.g. `exists_mem_ne_master_of_ne_bot`), an allowed Prop-level use of `Classical.choice`. **Axiom audit confirms the discipline:** the *data* (`0, check, fade2, fade, a, fixOf0`) is $\subseteq \{\text{propext}, \text{Quot.sound}\}$ (fully choice-free — `check`’s `inter_right` was rewritten from an initial `by_cases` to a direct `rcases` on the defining disjunction precisely to keep the data choice-free); only the packaged `OrderIso` (`fixIso`) and pure theorems (`isRetraction_a`, `example84a`) pick up `Classical.choice` through their Prop-valued proof fields (`left_inv/right_inv/map_rel_iff`), exactly mirroring the pre-existing `ext_of_toElementMap` pattern.

Example 8.4(b)

- **Mathematical Target:** Scott’s remarks after 8.4(a), same section (“EXAMPLES 8.4” is plural — these are two more worked uses of `check/fade`, not a mere aside, hence formalized as part of the same numbered item rather than skipped as a follow-up): (i) `strict : (D  $\rightarrow$  E)  $\rightarrow$  (D  $\rightarrow$  E)`, `strict(f) =  $\lambda x. fade(check(x), f(x))$` (`fade :  $0 \times E \rightarrow E$` this time), is a *projection* whose range is exactly the strict functions and is itself a domain; (ii) `smash(x, y) = fade(check(x), fade(check(y),  $\langle x, y \rangle$ ))` is a projection on $D \times E$ with range isomorphic to the smash product $D \otimes E$
- **Lean File:** `Scott1980/Neighborhood/Example84b.lean`
- **Proof Notes:** Both combinators reuse `check/fade` **verbatim**, reinstantiated at a second neighbourhood system (they were already generic over the ambient system in `Example84.lean`) — no new relation-level combinator is defined; the whole file is `comp/paired/proj/curry` bookkeeping plus closed-form calculations. `smash (smashRetraction := fade.comp(paired(check.comp proj0) smashFadeInner), smashFadeInner := fade.comp(paired(check.comp proj1) (idMap(prod D E))))` is identified with Proposition 8.2’s canonical retraction rather than analyzed from scratch: `smash_subsystem_prod : Exercise510.smash D E  $\triangleleft$  prod D E` (every smash neighbourhood is a product neighbourhood; a proper one stays proper under any intersection landing back in `prod D E`, via `Exercise510.inter_ne_master_left/right` — the same argument `Exercise510.smash`’s own closure proof uses), then `smashRetraction_eq_retractionOfSubsystem` proves `smashRetraction = Subsystem.retractionOfSubsystem` `smash_subsystem_prod` by matching closed forms (`smashRetraction_mem_iff`: “leave z alone unless a coordinate is $\perp$, else collapse to $\perp$ ” vs. `mem_toElementMap_retractionOfSubsystem` `smash`, Prop 8.2’s formula simplified using that z is already up-closed) — the one genuinely new argument is `exists_smash_witness`, a compactness calculation packing a *proper* smash-neighbourhood witness out of `z.fst/z.snd`’s `exists_mem_ne_master_of_ne_bot` witnesses intersected against any $Z \in z$ via the filter `inter_mem` of `z.fst/z.snd` (no

NeighborhoodSystem-level consistency witness needed, since z is already a filter). Once identified, `IsProjection`/the isomorphism to `Exercise510.smash D E` are inherited *for free* from Definition 8.3’s Subsystem corollaries (`isProjection_retractionOfSubsystem`, `elementIso`) — `example84b_smash.strict (strictRetraction := curry(fade.comp(paired(check.proj1) evalMap))`, using Theorem 3.12’s pre-existing `curry/evalMap` directly, no new function-space machinery) has closed form `toApproxMap_strictRetraction_mem: strict(f)(y) = ⊥_E if y=⊥_D else f(y)`, from `toElementMap_curry_apply` unfolded through `comp/paired/evalMap_apply/mem_toElementMap_fade` (the latter a same-file generalization of 8.4(a)’s `mem_toElementMap2_fade` from the fixed ambient D to an arbitrary codomain). From the closed form: f is a fixed point of `strict` iff $f(\perp)=\perp$, i.e. iff `Exercise510.IsStrict f (isStrict_toApproxMap_of_fixed/strictRetraction_fixed_of_isStrict`, via `Exercise510.isStrict_iff_apply_bot`); restricting `funSpaceEquiv` along this correspondence (`strictRetractionFixIso`, built directly rather than via `OrderIso` subtype-restriction API, using two standalone re-proofs `toFilter_toApproxMap/toApproxMap_toFilter` of `funSpaceEquiv`’s own round-trips to sidestep field-access friction) gives `Fix(strict)  $\simeq_o$  Exercise510.StrictMap D E`, composed with `Exercise510.strictFunEquiv.symm` for the isomorphism to `Exercise510.strictFun D E` — `example84b_strict`. **Axiom audit confirms the discipline:** the *data* (`smashRetraction`, `smashFadeInner`, `strictEvalFade`, `strictRetraction`) and the subsystem fact `smash_subsystem_prod` are $\subseteq \{\text{propxt}, \text{Quot.sound}\}$; the `IsRetraction/IsProjection/OrderIso` results pick up `Classical.choice` only through `by_cases/by_contra` case splits, exactly mirroring 8.4(a).

Theorem 8.5

- **Mathematical Target:** for $a:E \rightarrow E$, TFAE: (i) a is a finitary projection; (ii) $a(x) = \{Y \in E \mid \exists X \in x, X \subseteq Y \wedge XaX\}$ for all $x \in |E|$
- **Lean File:** `Scott1980/Neighborhood/Theorem85.lean`
- **Proof Notes:** Both directions proved, assembled as `finitaryProjection_iff_formula`. (ii) $\implies$ (i) (`isFinitaryProjection_of_formula`): `fixedNbhd a := {X ∈ E | XaX}` is a genuine subsystem $\triangleleft E$ for *any* a (`fixedNbhd_subsystem`, needs only `mono/inter_right`); formula (ii) unwound at principal elements via `rel_iff_mem_principal` reproduces `retractionOfSubsystem` `rel`’s formula exactly, giving $a = \text{retractionOfSubsystem } (\text{fixedNbhd_subsystem } a)$, so Def 8.3’s corollaries finish it. (i) $\implies$ (ii) (`formula_of_isFinitaryProjection`) is Scott’s hard direction, built on general algebraicity/compactness machinery for any `NeighborhoodSystem` (section `Algebraic: eq_iSupDirected_principal` — every element is the directed sup of its principal approximants; `IsCompactElt/eq_principal_of_isCompactElt` — `compact  $\leftrightarrow$  principal`). Given the `IsFinitary` witness $e:\text{Fix}(a) \simeq_o F.\text{Element}$, the induced “section” $i := \text{sectionMap } e:F \rightarrow E$ (via `ofMono`, Exercise 2.8, sending $\uparrow X \mapsto (e.\text{symm } \uparrow X).1$) is shown to realize $e.\text{symm}$ at *every* F -element, not just principals (`toElementMap_sectionMap`, Claim’: $\leq$ from `monotonicity+principal_le_of_mem`, $\geq$ from algebraicity of the target plus e ’s directed-sup-compatibility, `e_apply_iSupDirected_fixed`). This gives **Scott’s compactness-reflection fact** (`exists_principal_eq_of_isRetraction_le_idMap`): pulling a principal $\uparrow Y$ of F back through $e.\text{symm}$ always lands on a *principal* element of E — the key step lifts any E -directed bound on $(e.\text{symm } \uparrow Y).1$ to an a -fixed directed family via idempotency (`toElementMap_idem`), then transfers the bound back down using $a \leq \text{idMap } E$. Formula (ii) then follows directly: for $Y \in a(x)$, $w := a(x)$ is a -fixed (idempotency, no principality of x needed), Exercise 2.9’s union formula applied to `sectionMap e` at $e\langle w, _ \rangle$ finds W with $Y \in i(\uparrow W) = (e.\text{symm } \uparrow W).1$, compactness reflection turns this into $E.\text{principal } hX$ for some X with $X \subseteq Y$; XaX and $x.\text{mem } X$ both drop out of X ’s defining a -fixed equation and $\uparrow X \leq w \leq x$ ($a \leq \text{idMap } E$ again, deflationarily). Universe-polymorphic

throughout via one file-level `universe u` (shared by α, β , and the reusable Algebraic section's γ) to keep `IsFinitary`'s existential β unifiable with the general lemmas. **Choice-free:** `#print axioms finitaryProjection_iff_formula is  $\subseteq$  {proptext, Quot.sound}`.

Theorem 8.6(a)

- **Mathematical Target:** the `sub` combinator on $E \rightarrow E$: `sub f := retractionOfSubsystem (fixedNbhd f)` with $X \text{ sub}(f) Z \leftrightarrow \exists Y \in E, X \subseteq Y \wedge fY \wedge Y \subseteq Z$; `range(sub) = finitary projections on E`
- **Lean File:** `Scott1980/Neighborhood/Theorem86.lean`
- **Proof Notes:** Scott's formula is Prop 8.2 applied to Thm 8.5's `fixedNbhd f = {Y ∈ E | YfY}` (a genuine subsystem $\triangleleft E$ for *any* f , no hypotheses). Core per-token lemmas: `sub_rel` (unfolding); `sub_le` : `sub f ≤ f` (bare monotonicity: $X \subseteq Y, fY \subseteq Z \implies XfZ$); `fixedNbhd_sub` : `fixedNbhd(sub f) = fixedNbhd f` (witness $Y \subseteq Y' \subseteq Y \implies Y = Y'$); sharper idempotency `sub_sub` : `sub(sub f) = sub f` (equality, not just Scott's stated $\sqsubseteq$); `sub_mono`. **Range characterization, both directions:** easy containment `isFinitaryProjection_of_sub_eq_self` : `sub f = f  $\rightarrow$  IsFinitaryProjection f` (direct substitution into Def 8.3's `isFinitaryProjection retractionOfSubsystem`); hard containment `sub_eq_self_of_isFinitaryProjection` : `IsFinitaryProjection f  $\rightarrow$  sub f = f`, unblocked by Thm 8.5's hard direction — $\supseteq$ is `sub_le`, $\subseteq$ unwinds XfZ via `rel_iff_mem_principal` into $Z \in f(\uparrow X)$ and rewrites via `formula_of_isFinitaryProjection` into exactly `sub_rel`'s shape. Packaged as `sub_eq_self_iff_isFinitaryProjection`. Corollary `isFinitaryProjection_sub` : `IsFinitaryProjection(f)` for any f (feed `sub_sub` back through the iff). **Choice-free:** `#print axioms sub_eq_self_iff_isFinitaryProjection is  $\subseteq$  {proptext, Quot.sound}`.

Theorem 8.6(b)(i)

- **Mathematical Target:** `sub` is itself approximable, and a **projection**, on $(E \rightarrow E)$ — Scott's remark that " $f \mapsto \text{sub}(f)$ preserves directed unions of f 's, thus `sub` is itself approximable"
- **Lean File:** `Scott1980/Neighborhood/Theorem86.lean` (namespace `Sub8_6`); bridge lemma in `Scott1980/Neighborhood/Exercise213.lean`
- **Proof Notes:** `subFilter := toFilter ∘ sub ∘ toApproxMap` transports per-token `sub` along `funSpaceEquiv`; `subApprox` : `ApproximableMap(funSpace E E)(funSpace E E)` built via Exercise 2.13's `ofContinuous`. Needed new general lemma `continuous_of_monotone_iSupDirected` in `Exercise213.lean` (`monotone + directed-sup-preserving  $\implies$  topologically continuous`), proved from algebraicity (`eq_iSupDirected_principal`, kept local to avoid importing Thm 8.5). `subFilter_iSupDirected` needed *no* consistency argument: directed unions of *filters* correspond, under `toApproxMap`, to the raw union of the underlying maps' *relations* (`toApproxMap_rel_iSupDirected`, from `mem_iSupDirected`), and `sub_rel` is a *positive* existential in f 's relation, so it commutes with such unions by pure logic (`sub_toApproxMap_iSupDirected`). `IsRetraction subApprox/subApprox ≤ idMap` packaged as `isProjection_subApprox`, dropping out of `sub_sub/sub_le` via `toElementMap_subApprox`; proved via `le_antisymm` on `le_iff_toElementMap_le` (not the classical `ext_of_toElementMap`), to stay choice-free. **Choice-free:** `#print axioms isProjection_subApprox` (and friends: `isRetraction_subApprox`, `subApprox_le_idMap`, `continuous_subFilter`) is $\subseteq$ {proptext, Quot.sound}.

Theorem 8.6(b)(ii)

- **Mathematical Target:** sub is **finitary** on $(E \rightarrow E)$ — $\text{Fix}(\text{subApprox})$ (the finitary projections on E) is itself isomorphic to a domain
- **Lean File:** `Scott1980/Neighborhood/Theorem86.lean` (top level: `finitaryProjectionSubsystemEquiv` namespace `Sub8_6: subApproxFixIso, isFinitary_subApprox`); domain witness reused from `Scott1980/Neighborhood/Proposition611.lean`
- **Proof Notes:** The originally-flagged “circularity” (writing `subApprox = retractionOfSubsystem` h needs Thm 8.5 applied to `subApprox` itself) turned out to be avoidable: no witness of *that* shape is needed. Instead, Thm 8.6(a)’s existing bijection $f \mapsto \text{fixedNbhd } f/D \mapsto \text{retractionOfSubsystem } D$ between $\{f \mid \text{sub } f = f\}$ and $\{D \mid D \triangleleft E\}$ is upgraded from a bijection to a genuine **order-isomorphism** `finitaryProjectionSubsystemEquiv` : $\{f \mid \text{sub } f = f\} \simeq_o \{D \mid D \triangleleft E\}$: round trips are `fixedNbhd_retractionOfSubsystem (Y (retractionOfSubsystem h) Y) $\leftrightarrow$ $\exists W \in D, Y \subseteq W \subseteq Y$, and $Y \subseteq W \subseteq Y \implies W = Y$, so this is exactly $D.\text{mem } Y$) and sub’s own defining equation (sub_retractionOfSubsystem); order is preserved/reflected via retractionOfSubsystem rel’s witness clause being monotone in the subsystem argument, packaged through Subsystem.subsystem iff_subset_of_common. Separately, $\text{Fix}(\text{subApprox}) \simeq_o \{f \mid \text{sub } f = f\}$ (subApproxFixIso) unfolds subApprox.toElementMap $\varphi = \varphi$ via toElementMap_subApprox/subFilter into sub(toApproxMap φ) = toApproxMap φ , transported by toApproxMap/toFilter’s round trips (toApproxMap_subFilter, toFilter_toApproxMap), with order transported via funSpaceEquiv.ma rel_iff. Composing both with Lecture VI’s Proposition 6.11 (subsystemReprIso : $\{D \mid D \triangleleft E\} \simeq_o (\text{reprSystem}(\text{subFam } E) \dots).\text{Element}$ — the subsystems of E already form a domain, proved independently via Exercise 2.22’s abstract representation theorem) gives isFinitary_subApprox directly: no new “domain of subsystems” (universal-domain) construction was needed, since Prop 6.11 had already built exactly that domain in Lecture VI. isFinitaryProjection_subApprox packages this with 8.6(b)(i)’s isProjection_subApprox. Axioms: finitaryProjectionSubsystemEquiv/subApproxFixIso and their supporting lemmas (fixedNbhd_retractionOfSubsystem, sub_retractionOfSubsystem) are $\subseteq \{\text{propext}, \text{Quot.sound}\}$; isFinitary_subApprox/isFinitaryProjection_subApprox pick up Classical.choice solely through Prop 6.11’s subsystemReprIso (itself inheriting it from Exercise 2.22’s reprIso, the documented “for set theorists” exercise) — the same provenance as every other domain-representation result in this project (Ex 3.25/3.27, Prop 6.11 itself).`

Theorem 8.6(c)

- **Mathematical Target:** if E is effectively given, then sub is **computable**
- **Lean File:** `Scott1980/Neighborhood/Theorem86c.lean`
- **Proof Notes:** Mirrors Theorem 7.6’s `fixMap_isComputable` template, but is shorter since `sub`’s formula has a single existential (no iteration/chain). `subApprox := ofContinuous subFilter ...` unfolds via `ofMono/toFilter` to `subApprox.rel F G $\leftrightarrow$ (funSpace E E).mem G $\wedge$ sub(toApproxMap $\uparrow$ F) $\in$ G (subApprox_rel_iff, using proof irrelevance to drop the membership-witness existential). Specializing $F = \text{Xenum } n$, $G = \text{Xenum } m$ and unfolding via mem_Xenum_iff_map (Thm 7.5) gives subApprox_rel_Xenum_iff: $(\text{Xenum } n) \text{subApprox}(\text{Xenum } m) \leftrightarrow g_N m = 1 \rightarrow \forall e \in \text{decodeList } m, (\text{sub } \hat{g}_n).\text{rel}(X_{\{e.1\}})(X_{\{e.2\}})$ with $\hat{g}_n := \text{toApproxMap}\uparrow(\text{Xenum } n)$ the least map. sub_rel’s existential witness Y is reindexed to a presentation index y via P.surj (sub_rel_iff_exists_index), and the key decidability step reuses Theorem 7.6’s own leastMap_Xenum_rel/Xenum_codePair unchanged: $\hat{g}_n.\text{rel}(X_y)(X_y) \leftrightarrow \text{Xenum } n \subseteq \text{Xenum}(\text{codePair } y \ y) (\text{sub_leastMap_rel_iff})$, exactly the function-space presentation’s own decidable incl_computable. subStep_recDecidable packages the per-witness triple $(\text{Xenum } n \subseteq \text{Xenum}(\text{codePair } y \ y) \wedge X_{$`

$\{e.1\} \subseteq X_y \wedge X_y \subseteq X_{\{e.2\}}$) as one `RecDecidable` (coded $w = \langle y, \langle n, e \rangle \rangle$, `RecDecidable.and` of three reindexed presentation chars); `.re.proj` (unbounded $\exists y$ of decidable $\implies$ r.e.) + `REPred.forall_mem_decodeList2` (bounded $\forall e \in \text{decodeList } m$, parameterised in n) + `.or/Decidable.imp_iff_not_or` (guard by $\neg(\text{gN } m = 1)$) assembles `subApprox_isComputable` : `IsComputableMap`(`funPresentation P P...`)(`funPresentation P P...`) `subApprox.sub_isComputable_of_isEffectivelyGiven` packages Scott’s literal statement, extracting P ’s own chars via `funConsChar/funPresentation` (Thm 7.5’s own construction, reused verbatim) exactly as `funSpace_isEffectivelyGiven` does. **Choice-free in full:** `#print axioms on subApprox_isComputable/sub_isComputable_of_isEffectivelyGiven` and all supporting lemmas is $\subseteq \{\text{propext}, \text{Quot.sound}\}$ — no `Classical.choice` anywhere (unlike 8.6(b)(ii), whose choice provenance is untouched here).

Definition 8.7

- **Mathematical Target:** the neighbourhood system U over $[0,1] \subseteq \mathbb{Q}$: non-empty finite unions of rational intervals $[r,s)$ with $0 \leq r < s \leq 1$
- **Lean File:** `Scott1980/Neighborhood/Definition87.lean`
- **Proof Notes: Encoding.** A finite union of intervals is coded by `L : List (Q × Q)` (`presentedIntervals L := ⋃ p ∈ L, Ico p.1 p.2`); rather than force the per-pair bounds $0 \leq r < s \leq 1$ into every list operation, `U.mem X := (∃ L, X = presentedIntervals L) ∧ X.Nonempty ∧ X ⊆ Ico 0 1` — presentability plus the two set-level facts Scott’s family actually needs. **Closure under $\cap$ is bookkeeping-free:** pairwise-combining two lists’ endpoints via `p.1 ⊔ q.1, p.2 ⊔ q.2` (`combineIntervals`) always presents the intersection (`presentedIntervals_inter`, proved directly from `sup_le/lt_inf_iff/le_sup_left/inf_le_left`-style order facts — no case split on validity, since a crossed bound `⊔ ≥ ⊔` just makes `Ico` empty on its own). `master_mem/sub_master/inter_mem` (`Z.Nonempty.mono hZsub, Set.inter_subset_left.trans hXsub`) are then immediate. **Faithfulness** (`U.mem_iff_scott`): the encoding is *not* a relaxation — it is proved equivalent to Scott’s literal per-pair-bounded family, by clipping any presenting list to $[0,1]$ (`clip p := (p.1 ⊔ 0, p.2 ⊔ 1)`, `presentedIntervals_map_clip : presentedIntervals(L.map clip) = presentedIntervals L ∩ Ico 0 1`) and discarding now-degenerate pairs (`presentedIntervals_filter_lt`, filtering on `decide(p.1 < p.2)` doesn’t change the union since dropped pairs contributed $\emptyset$ already). **Bonus — Scott’s remark “U has no minimal neighbourhoods”** (`U_no_minimal`): any U -neighbourhood X splits into two disjoint proper U -neighbourhoods by cutting at the rational midpoint $m := (p.1 + p.2)/2$ of any witnessing interval $[p.1, p.2] \subseteq X$ (`left_lt_add_div_two/add_div_two_lt_right`) — $Y := X \cap Iio\ m$, $Z := X \cap Ici\ m$ are both presentable (`clipLt/clipGe` variants of the same clipping trick), non-empty ($p.1 \in Y$, $m \in Z$), disjoint, union to X , and each properly smaller than X (else the other would collapse into the empty intersection). **Axiom footprint.** Every proof is elementary list recursion plus $\mathbb{Q}$ ’s linear order — no `Classical.choice/Classical.dec` is used directly — but `#print axioms` reports `[propext, Classical.choice, Quot.sound]` throughout, because the *pinned Mathlib*’s bundled `LinearOrder Q` (`Rat.instLinearOrder`) is itself `Classical.choice`-tainted at the axiom level in this snapshot: even bare `Rat.le_refl` reports this footprint (confirmed directly), as does the pre-existing `Exercise117.lean`’s `ratIntervalMem_nonempty` despite that file’s now-stale “choice-free” docstring claim. This is an upstream $\mathbb{Q}$ -order-hierarchy artifact, not a choice made here.

Theorem 8.8(a)

- **Mathematical Target:** for every countable neighbourhood system $D, D \trianglelefteq U$ (general/non-effective case: $\exists D' : \text{NeighborhoodSystem } \mathbb{Q}, D \cong^D D' \wedge D' \triangleleft U$)

- **Lean File:** Scott1980/Neighborhood/Theorem88.lean (atom/transfer apparatus) + Scott1980/Neighborhood/Theorem88a.lean (assembly, theorem_8_8_a)
- **Proof Notes:** Scott’s back-and-forth construction, fully assembled. **Atom apparatus** (Theorem88.lean): generic `genAtom Z M δ n/atomD`, a totalized `splitChoice` packaging `exists_split` (built from **Definition 8.7’s** `U_no_minimal`, no interval-difference-closure lemma needed — the three cases are handled entirely by $\emptyset$, B itself, or `U_no_minimal`’s output), the recursive `atomU`, and the combined invariant `atomU_invariant` (emptiness-match/`U.mem-or- $\emptyset$` /pairwise disjointness). `Yseq n` is the union of the depth- $(n+1)$ “+”-pieces (`Fin n → Bool-indexed`), shown to satisfy `atomU_eq_genAtom : atomU = genAtom Yseq U.master`. This yields the **general finite-constraint transfer lemma** `transfer_empty_iff` (a listed Boolean-constraint set on Δ is non-empty iff the corresponding one on `U.master` is) and its corollaries `transfer_subset_iff/transfer_inter_empty_iff/transfer_double_subset_iff/transfer_inter_eq_iff` (the last upgrading an *equation* $X_i \cap X_j = X_k$ to $Y_i \cap Y_j = Y_k$, both directions), plus `Yidx`-independent nonemptiness facts `Yseq_nonempty_of_mem/Yseq_empty_or_mem/Yseq_zero_eq_master`. **Assembly** (Theorem88a.lean): the naive “feed D ’s own enumeration X_n directly into `Yseq`” **does not work** — `Subsystem.inter_closed` demands that whenever $Y_i \cap Y_j$ is merely non-empty as a raw set (which, since U is so permissive, is exactly when it’s a genuine U -neighbourhood), $X_i \cap X_j$ must *already* be a D -neighbourhood, and this can fail for perfectly good D where X_i, X_j overlap as raw sets without being *witnessed-consistent* (confirmed with an explicit 3-element counterexample $D=\{\Delta, X_1, X_2\}$ over $\Delta=\{1,2,3\}$). This is exactly the gap Scott’s own “ $WLOG D \cong D^\dagger$ ” preparation (Definition 7.9’s $\downarrow X \cap \downarrow Y = \downarrow (X \cap Y)$, empty iff *not consistent*) is for — **implemented here not as a NeighborhoodSystem on down-sets but as a reindexing over $\mathbb{N}$** : `idxSet e n := {m | e m  $\subseteq$  e n}` (Scott’s $\downarrow(e n)$, but tracked purely by index) is *always non-empty* ($n \in \text{idxSet } e n$), matches e ’s inclusion order exactly (`idxSet_subset_iff`), and $e i \cap e j = e m \rightarrow \text{idxSet } e i \cap \text{idxSet } e j = \text{idxSet } e m$ is a **definitional** rewriting needing no transfer at all. Feeding `(idxSet e, Set.univ)` into `Yseq` gives `Yidx`, and `embed_subset_iff/embed_eq_iff` (from `transfer_subset_iff`) show $e i \subseteq e j \leftrightarrow Yidx\ e\ i \subseteq Yidx\ e\ j$. `DprimeU (mem Y :=  $\exists n, Y = Yidx\ e\ n$ )` then gets both its own `inter_mem` and `DprimeU_subsystem`’s `inter_closed` from a single shared lemma pair `exists_inter_index_of_dmem/exists_inter_index_of_nonempty`, which pull a witnessed-consistent pair out of D ’s own `inter_mem` (using nonemptiness-transfer to *find* the witness when only raw non-emptiness is known) and push the resulting equation $e i \cap e j = e m$ across to $Yidx\ e\ i \cap Yidx\ e\ j = Yidx\ e\ m$ via `transfer_inter_eq_iff`. The element-level isomorphism `domainIso : D.Element  $\simeq$  DprimeU.Element` is a direct pushforward/pullback-filter construction (`toDprimeU/toD`, mirroring the codebase’s `tokenIso/powerIso` idiom), with `embed_eq_iff` resolving index-choice ambiguity. `theorem_8_8_a` supplies the enumeration e from `[Countable {S//D.mem S}]` via `exists_surjective_nat`, shifted by one and patched at 0 to enforce $X_0 = \Delta$. **Axiom footprint:** `#print axioms theorem_8_8_a reports [propext, Classical.choice, Quot.sound]` — expected and unavoidable, since this is a genuinely non-constructive Prop-level existence statement for an arbitrary countable D (`Classical.choice` enters both via `exists_surjective_nat` and `exists_split`’s use of `U_no_minimal`’s witness).

Theorem 8.8(b)

- **Mathematical Target:** if D is effectively given, the projection pair witnessing $D \leq U$ (Theorem 8.8(a)) can be taken computable
- **Lean File:** — (umbrella; see sub-items 8.8(b)(i)–8.8(b)(viii) below for the per-part Lean files)

- **Proof Notes:** the effective refinement of 8.8(a)’s construction, broken into an 8-part plan for tractability, tracked as sub-rows **8.8(b)(i)–8.8(b)(viii)**. **(i)–(vi) are Pass:** choice-free $\mathbb{Q}/\mathbb{Z}$ Gödel encoding + comparison arithmetic (i); `List( $\mathbb{Q} \times \mathbb{Q}$ )`-code interval algebra (`combineIntervals/difference`) + subset/eq/nonempty decidability (ii); `U.IsEffectivelyGiven` assembled as a genuine `ComputablePresentation` (iii); an explicit deterministic `splitU` replacing `U_no_minimal`’s existential witness (iv); D-side atom-emptiness (`DAtom_recDecidable`) for an arbitrary `ComputablePresentation`, choice-free at the `Nat.Primrec` core (v); and Theorem 8.8(a)’s **own already-built classical D'** (`DprimeU`) shown to be effectively given outright, by reducing its index relations to facts already decided by (v)/(vi)’s predecessors rather than by computing explicit U-codes for `Yidx e n` (vi) — this sidesteps an earlier-documented design obstruction (see `HANDOFF.md`’s 2026-07-02 “Warning: Design pitfall”/resolution entries) about an effective splitter `splitEff` provably tracking the same split an `atomUCode` recursion would use. **(vii) is now Pass in full**, split into sub-rows **8.8(b)(vii)(1)–8.8(b)(vii)(4)** (a fresh code-native back-and-forth construction, `Theorem88d.lean/Theorem88e.lean/Theorem88f.lean`, needed after a correction: (vi)’s `DprimeUPresentation` alone does not unblock `IsComputableMap` — see (vii)’s row: the foundational recursion, per-step correctness, the `atomUCode` invariant (validity + restricted disjointness), `YseqCode`’s closed form, the D'' assembly ($D \cong^D D''$, $D'' \triangleleft U$, `ComputablePresentation D''`), and finally (vii)(4)’s headline claim — D'' ’s own projection pair (`Subsystem.inj/Subsystem.proj`) witnessing $D'' \triangleleft U$ is `IsComputableMap` in both directions, which turned out to need **no new decidability core at all**: both relations collapse (once each side’s `mem`-clause is discharged automatically from its own presentation) to a single already-generic fact, `ComputablePresentation.incl_computable`, reindexed along `YseqCode P` in one argument or the other. **(viii) is now Pass:** the final assembly `theorem_8_8_b` (`Theorem88g.lean`) packages Parts 7(3)/7(4)’s ingredients into a single existential — no new mathematical content. **Theorem 8.8(b) is now fully Pass, all 8 parts done. Axiom discipline throughout (i)–(vi):** every `Nat.Primrec`/decidability core result is $\subseteq \{\text{propext}, \text{Quot.sound}\}$ (fully choice-free), with `Classical.choice` appearing only in documented, unavoidable places — the *pinned Mathlib*’s $\mathbb{Q}$ -order-instance taint (inherited from Definition 8.7, not introduced here), a single excluded-middle step in `DAtom_eq_empty_iff`’s `Prop`-level characterization (v), and `splitChoice`’s classical witness extraction underlying `DprimeU` itself (inherited from Theorem 8.8(a), not newly introduced by (vi)) — never inside any computable core.

Theorem 8.8(b)(i)

- **Mathematical Target:** Part 1 of 8 — choice-free Gödel numbering of $\mathbb{Z}/\mathbb{Q}$ plus primitive-recursive comparison arithmetic, for use throughout the rest of the effective refinement
- **Lean File:** `Scott1980/Neighborhood/RationalPrimrec.lean`
- **Proof Notes:** a choice-free Gödel numbering of $\mathbb{Z}$ (difference-pairs `encodeInt/decodeInt`, exact round trip for *every* z , no canonicity side-condition) and $\mathbb{Q}$ (`encodeRat q := pair (encodeInt q.num) (q.den-1)`, exact round trip via `Rat.mkRat_self`), plus primitive-recursive comparison arithmetic `ratLeCode/ratLtCode/ratMaxCode/ratMinCode` (cross-clearing denominators via *addition* only, avoiding truncated-subtraction case splits) with full `Nat.Primrec` + correctness (`_eq_one_iff`) proofs, and a packaged `ratLtCode_recDecidable2 : RecDecidable2 ( $\cdot < \cdot$ )` for reuse with `Recursive.lean`’s closure combinators.

Theorem 8.8(b)(ii)

- **Mathematical Target:** Part 2 of 8 — `List( $\mathbb{Q} \times \mathbb{Q}$ )`-code encoding of presented interval-unions, code-level `combineIntervals/difference`, and subset/equality/nonemptiness decidability at the code level

- **Lean File:** `Scott1980/Neighborhood/RecursiveCross.lean` + `Scott1980/Neighborhood/IntervalP`
- **Proof Notes:** generic `Nat.Primrec` list-code combinators `crossCombine/flatMapCode` (new, in `RecursiveCross.lean`); `List(Q×Q)` encoding (`encodeQPairList/decodeQPairList`, exact round trip, via `Recursive.lean`’s `encodeList`); code-level `combineCode` realizing `combineIntervals` (`presentedIntervals_decodeQPairList_combineCode`); code-level interval *difference* `diffCode` (built from the unconditional identity `Ico_diff_Ico : Ico a b \ Ico c d = Ico a (b ⊔ c) ∪ Ico (a ⊔ d) b`, lifted through `diffOneList→diffSingleList→diffA` at the list level and mirrored at the code level via `flatMapCode/foldCode`, `presentedIntervals_decodeQPairList_diffCode`); and the **decidability layer**: non-emptiness of a presented union reduces to a bounded- $\exists$ over the list (`presentedIntervals_nonempty_iff`, `qpNonemptyChar` via `Recursive.lean`’s `existsListChar` — needed a new generic `existsListChar_le_one` bound lemma, added there, mirroring the existing `allListChar_le_one`), giving `recDecidable_presentedIntervals_nonempty`; subset/equality then reduce for free to non-emptiness of `diffCode` (`recDecidable2_presentedIntervals_subset` via `Set.diff_eq_empty`, `recDecidable2_presentedIntervals_eq` via `Set.Subset.antisymm_iff` and `Recursive.lean`’s `RecDecidable2.swap`) — no new arithmetic needed for either.

Theorem 8.8(b)(iii)

- **Mathematical Target:** Part 3 of 8 — assemble a genuine `ComputablePresentation` of `U` (`U.IsEffectivelyGiven`)
- **Lean File:** `Scott1980/Neighborhood/UComputablePresentation.lean`
- **Proof Notes:** List-level canonicalization `canonList` (clip every pair into $[0,1]$ via `qpClip`, filter degenerate pairs, fall back to `U.master`’s literal $[(0,1)]$ if empty) is *always* a valid `U`-presentation (`U_mem_presentedIntervals_canonList`) and is the *identity* on already-valid input (`canonList_fixed`); mirrored step-by-step at the code level as `canonCode` (`qpClipCode/canonFilterStep/canonListCode/canonCode`, all `Nat.Primrec`), bridged by the single lemma `presentedIntervals_decodeQPairList_canonCode`. The enumeration `UX n := presentedIntervals(decodeQPairList(canonCode n))` is total, always a neighbourhood (`U_mem_UX`), and surjective onto `U`’s neighbourhoods (`U_surj_UX`, via `U_mem_iff_scott + canonList_fixed`). **Key simplification:** Scott’s consistency side condition $\exists k. X_k \subseteq X_n \cap X_m$ is *equivalent* to plain non-emptiness of $X_n \cap X_m$ (`U_cons_iff_nonempty_inter` — every X_k is itself non-empty, and a non-empty $X_n \cap X_m$ is automatically some `U`-neighbourhood by surjectivity), collapsing both `interEq_computable` and `cons_computable` directly onto Part 2’s `recDecidable2_presentedIntervals_eq/recDecidable_presentedIntervals_nonempty` composed with `combineCode○canonCode` reindexing. `inter n m := combineCode(canonCode n)(canonCode m)` (no outer `canonCode` — `UX` already re-canonicalizes on lookup); `masterIdx := encodeQPairList [(0,1)]`.

Theorem 8.8(b)(iv)

- **Mathematical Target:** Part 4 of 8 — an explicit deterministic `splitU` replacing Definition 8.7’s `U_no_minimal` existential midpoint-split
- **Lean File:** `Scott1980/Neighborhood/SplitU.lean`
- **Proof Notes:** Since Part 3 already showed every pair in `canonCode n`’s decoded list is non-degenerate (`p.1 < p.2`), `splitU` needs no existential search: it deterministically takes the list’s *first* pair (`firstElemCode`) and its midpoint (`ratMidCode`, new in `RationalPrimrec.lean` — division-free, cross-clearing denominators then doubling the denominator rather than computing a gcd-reduced fraction), then clips the whole canonical list left/right of that

midpoint (public `qpClipLt/qpClipGe` re-declarations of `Definition87.lean`’s file-private `clipLt/clipGe`, lifted to lists via `RecursiveCross.lean`’s `flatMapCode` used as a generic “map with fixed parameter” combinator — `splitULeft n := clipLtListCode (splitMidCode n) (canonCode n)`, similarly `splitURight`). `UX_splitULeft/UX_splitURight` show $UX(\text{splitULeft } n) = X_n \cap I_{io} m / UX(\text{splitURight } n) = X_n \cap I_{ci} m$ outright (the clipped list is already a valid presentation, so `canonList_fixed` makes re-canonicalization a no-op), from which the four Scott properties (`splitU_disjoint/splitU_union/splitU_left_ne/splitU_right_ne`) follow by the same interval algebra as `U_no_minimal`, plus one extra observation (`U_mem_UX`: every X_k is non-empty) to rule out either half degenerating to the whole. `primrec_splitULeft/primrec_splitURight` are fully choice-free.

Theorem 8.8(b)(v)

- **Mathematical Target:** Part 5 of 8 — for an arbitrary `ComputablePresentation` of D , deciding whether a finite Boolean atom-constraint on D ’s neighbourhoods is satisfiable (Theorem 8.8(a)’s $(\diamond)$ trick, made decidable)
- **Lean File:** `Scott1980/Neighborhood/DAtomDecidable.lean`
- **Proof Notes:** For an arbitrary `ComputablePresentation` P of D , reindexes Theorem 8.8(a)’s $(\diamond)$ D -atoms over $\mathbb{N}$ via `idxSet` (`Theorem88a.lean`): $IPos\ P\ pos := \{m \mid \forall i \in pos, P.X\ m \subseteq P.X\ i\}$ ($= \text{idxSet } i_1 \cap \dots$ via `IPos_cons`), $DAtom\ P\ pos\ neg := IPos\ P\ pos \cap \{m \mid \forall j \in neg, P.X\ m \not\subseteq P.X\ j\}$. The positive meet is computed by a fold (`meetStep/meetFold`) threading a single `Nat.pair(ok, idx)`-coded accumulator through `pos`, using `P.inter/cons_computable` at each step and short-circuiting to “not ok” the moment two constraints are P -inconsistent (`meetStep_spec/meetFold_spec`: the final state faithfully represents $IPos\ P\ pos$, either as `idxSet idx` or, on `ok=0`, as $\emptyset$). `DAtom_eq_empty_iff` reduces atom-emptiness to “(meet inconsistent) $\vee (\exists j \in neg, \text{meet’s } idx \subseteq P.X\ j)$ ”; `DAtomEmptyChar` packages this as `Nat.Primrec` (`meetFoldCode/meetStepCode` mirroring the fold at the code level via `foldCode`, guarded by `selectFn` and `existsListChar` against `incl_computable`); `DAtom_recDecidable` is the final `RecDecidable2` statement, extracting P ’s two deciders inside the `Prop`-valued goal (`Proposition710.lean`’s pattern) to keep the statement polymorphic in P . **Axiom bisection found and fixed 3 real choice-taint bugs** (see `HANDOFF.md` 2026-07-02 entry for full detail): (i) Mathlib’s `Nat.Primrec.id` vs. the project’s own choice-free `primrec_id` — same statement, different (taint-free) proof term; (ii) a `simp/norm_num`-closed case split replaced by explicit `rw` chains; (iii) the generic pitfall that **omega closing a vacuous implication whose conclusion is a non-arithmetic (Set) equality silently pulls in Classical.choice** — fixed everywhere by `intro h; exact absurd h (by decide)` instead. After these fixes, `meetStep_spec/meetFold_foldl_spec/meetFold_spec/primrec_meetStepCode/primrec_meetFoldCode/primrec_DAtomEmptyChar` are all $\subseteq \{\text{propext}, \text{Quot.sound}\}$ — genuinely choice-free, matching `Proposition710.lean`’s `primrec_interCode` precedent. Only the outer `Prop`-level `DAtom_eq_empty_iff/DAtomEmptyChar_eq_one_iff/DAtom_recDecidable` retain `Classical.choice`, from a `by_contra` on an undecidable existential over α (excluded middle needed to extract a witness j from “not empty”, never used inside `DAtomEmptyChar` itself or its `Nat.Primrec` proofs) — a documented, unavoidable instance per the project’s choice-discipline exception.

Theorem 8.8(b)(vi)

- **Mathematical Target:** Part 6 of 8 — the recursive Y_n -chain (Theorem 8.8(a)’s Y_{idx}) as an effective witness/verifier construction, combining Part 4’s `splitU` with Part 5’s `DAtom_recDecidable`

- **Lean File:** `Scott1980/Neighborhood/Theorem88.lean` (generalized over an abstract `split`) + `Scott1980/Neighborhood/Theorem88b.lean` + `Scott1980/Neighborhood/Theorem88c.lean`
- **Proof Notes: Sub-steps 6a–6c:** **6a — generalize Theorem88.lean over an abstract `split`.** Introduced `SplitSpec split : Prop` (exactly `exists_split`’s conclusion, packaged as a `Prop` about a *total* function `split : Set α $\rightarrow$ Set $\mathbb{Q}$ $\rightarrow$ Set $\alpha \rightarrow$ Set $\mathbb{Q} \times$ Set $\mathbb{Q}$); splitChoice_isSplitSpec recovers the classical instantiation. Every downstream definition/theorem from atomU through Yseq_nonempty_of_mem (atomU, Yseq, atomU_invariant, all transfer_*/Yseq_* lemmas) is now parametrized over (split, hsplit : SplitSpec split) rather than hardcoding splitChoice; Theorem88a.lean updated to instantiate the general apparatus with splitChoice/splitChoice_isSplitSpec explicitly at every call site, confirming Theorem 8.8(a) still builds unchanged from the reader’s point of view. 6b (Theorem88b.lean) — re-pointing an effective presentation’s 0-th index at its master. Theorem88a.lean’s Yidx/DprimeU/domainIso machinery needs e 0 = D.master (Scott’s $X_0 = \Delta$ convention); an arbitrary ComputablePresentation P need not have P.masterIdx = 0. Added a fully general utility ComputablePresentation.reindexInvo (Definition71.lean): given Nat.Primrec φ with Function.Involutive φ , transports every field of a presentation along φ ($X' \ n := P.X (\varphi \ n)$) by composing each decider with the pairwise- φ -reindexing code (RecDecidable.comp), choice-free. eIdx (swap 0 $\leftrightarrow$ P.masterIdx) is the one used here; P0 := P.reindexInvolutive eIdx ... then gives e := P0.X with he0 : e 0 = D.master and hcover for free. 6c — genAtom (idxSet e)-emptiness reduces to DAtom-emptiness. posnegList $\delta \ n$: List $\mathbb{N} \times$ List $\mathbb{N}$ mirrors genAtom’s own recursion step-for-step, so genAtom_eq_DAtom : genAtom (idxSet e) Set.univ $\delta \ n$ = DAtom P0 (posnegList $\delta \ n$).1 (posnegList $\delta \ n$).2 composes with Part 5’s DAtom_recDecidable P0 with zero new decidability machinery. 6d/6e (Theorem88c.lean, new) — the resolution: never compute Yidx e n’s value as a code at all. The originally-planned splitEff/atomUCode route hit a genuine wall (splitULeft/splitURight split against the specific code fed in, not the abstract set, so no code-only tracker can be proved to agree with a Classical.choice-extracted set-level splitEff — full writeup preserved in HANDOFF.md’s “Warning: Design pitfall” entry for the record). The obstruction is dissolved, not overcome: ComputablePresentation.X : $\mathbb{N} \rightarrow$ Set α is data, not required to be code-computable (unitPresentation’s constant X is the existing precedent) — only the two index relations need be decidable. So Part 6 instead shows Theorem 8.8(a)’s own already-built classical D' (DprimeU D (e P) ..., unchanged, still built via splitChoice) is itself effectively given: Yidx e i $\cap$ Yidx e j = Yidx e k transfers (transfer_inter_eq_iff) to idxSet e i $\cap$ idxSet e j = idxSet e k, which a new lemma idxSet_inter_eq_iff_DAtom reduces to (e k $\subseteq$ e i) $\wedge$ (e k $\subseteq$ e j) $\wedge$ (DAtom (P0 P) [i,j] [k] = $\emptyset$) — two incl_computable queries plus one fixed-shape DAtom_recDecidable query, packaged via DAtom_pair_recDecidable (reindexing DAtom_recDecidable (P0 P) along Nat.Primrec codes capPosCode/capNegCode for the constant-shape lists [i,j]/[k]); $\exists k, Yidx e k \subseteq Yidx e i \cap Yidx e j$ transfers (embed_subset_iff, twice) to $\exists k, e k \subseteq e i \wedge e k \subseteq e j$, literally (P0 P).cons_computable’s own predicate reused verbatim; the intersection index is literally (P0 P).inter n m reused as-is (idxSet_inter_of_inter_eq); master index is 0 (Yidx_zero). These assemble into DprimeUPresentation : ComputablePresentation (DprimeU D (e P) (hcover P) (he0 P)) and DprimeU_isEffectivelyGiven, completing Part 6 with no new splitting operation, no canonical-form normalization, and no exponential atom-union machinery. Pitfall: rw [transfer_inter_eq_iff ..., idxSet_inter_eq_iff_DAtom ...] failed with “pattern not found” inside a RecDecidable.of_iff (fun t => ?_) ... goal, because the goal is an un-beta-reduced lambda application; dsimp only immediately before the rw chain fixes it (general lesson for any RecDecidable.of_iff (fun t => ?_) goal in this codebase). Axiom footprint: all Nat.Primrec de-`

ciders $\subseteq \{\text{propext}, \text{Quot.sound}\}$; the outer Prop-level results (`idxSet_inter_eq_iff_DAtom` through `DprimeU_isEffectivelyGiven`) carry `Classical.choice`, but this is **not new taint** — `DAtom_recDecidable` (Part 5) and `theorem_8_8_a` (Theorem 8.8(a) itself) already carry it at exactly this level (confirmed by direct `#print axioms` comparison), inherited from `splitChoice`’s classical witness extraction, not introduced by this file.

Theorem 8.8(b)(vii)

- **Mathematical Target:** Part 7 of 8 — the projection pair $i, j : \text{ApproximableMap } D \rightarrow U$ (Theorem 8.8(a)’s `domainIso`-derived pair) satisfy `IsComputableMap`
- **Lean File:** — (umbrella; see sub-items 8.8(b)(vii)(1)–8.8(b)(vii)(4) below for the per-part Lean files)
- **Proof Notes: Correction of an earlier plan:** (vi)’s `DprimeUPresentation` alone does *not* unblock this part — it only shows D ’s own index relations decidable, never which U -code `Yidx e n` (a `Classical.choice`-picked value, via `splitChoice`) actually sits at, so the needed cross-relation $Yidx e n \subseteq UX m$ cannot be shown r.e. from it. The fix, underway in new file `Theorem88d.lean`: abandon `Theorem88.lean`’s generic `Set`-valued `atomU/split` machinery for this part entirely (a `Set`-valued `split` can never be proved to match an independent code tracker — a set has many codes) and build the **whole back-and-forth recursion natively as a `Nat.Primrec` function of $(\text{depth}, \text{bit-source})$** , threading an explicit U -code through the state from step zero. **Done so far, lake build green, zero sorry:** the packed-state recursion `atomUCodeState/atomBase/atomStep` (mirroring `exists_split`’s three cases — empty/empty/genuine-split — via `datumDec` (Part 5’s `DAtom_recDecidable`, extracted) and `splitULeft/splitURight` (Part 4), all `Nat.Primrec`; and the headline **per-step correctness theorem `genAtom_atomUCode`**: the accumulated (pos, neg) -code pair at depth n for bit-source k tracks *exactly* the same D -side atom as `genAtom (idxSet (e P)) Set.univ (deltaOf k) n` (proved via new `DAtom_cons_pos/DAtom_cons_neg`, mirroring `Theorem88b.lean`’s `genAtom_eq_DAtom` but prepend- rather than append-based). This foundational recursion + per-step correctness is the prerequisite for all four sub-parts below (see `HANDOFF.md`’s 2026-07-02 “correction” entry for the full plan this split is based on).

Theorem 8.8(b)(vii)(1)

- **Mathematical Target:** The `atomUCode` invariant, mirroring `Theorem88.lean`’s `atomU_invariant` but proved fresh at the code level — **restated** (see Proof Notes for why) as: (validity) $U.\text{mem } (UX (\text{atomUCode } P \ n \ k))$ unconditionally; (disjointness) if $\text{deltaOf } k / \text{deltaOf } k'$ disagree at some $j < n$ and **both bit-sources are still D -side non-empty at depth n** (`atomUEmpty P n k = 0, atomUEmpty P n k' = 0`), then $UX (\text{atomUCode } P \ n \ k) \cap UX (\text{atomUCode } P \ n \ k') = \emptyset$
- **Lean File:** `Scott1980/Neighborhood/Theorem88d.lean`
- **Proof Notes:** The originally-planned “(a) match” clause (`DAtom =  $\emptyset \leftrightarrow UX (\text{atomUCode } \dots) = \emptyset$`) is **impossible to state, let alone prove**: unlike `Theorem88.lean`’s `atomU` (genuine `Set Q`-valued, where $\emptyset$ is an honest value), $UX : \mathbb{N} \rightarrow \text{Set } Q$ is a **total surjection onto U ’s neighbourhoods** (`U_mem_UX`, unconditional — `canonCode`’s degenerate-input fallback is `U.master`, never $\emptyset$); no code represents the empty set, so the RHS of “(■)” is simply always false. This makes **validity free** (`atomUCode_mem := U_mem_UX _`, no induction needed) and forces **disjointness to be restricted** to non-empty atoms: once a bit-source’s atom is D -side empty, `atomUCode_eq_zero_of_empty` shows its code is frozen at the junk value 0 forever (both hypothetical continuations of an

empty atom are themselves empty, by `DAtom_cons_pos/DAtom_cons_neg`-monotonicity), so *every* junk atom aliases to the same `UX 0` and disjointness genuinely fails there — but (vii)(2)’s `YseqCode` union filters junk `k`’s out, so this restricted form is exactly what’s needed. Built (`datomDec` first strengthened to be literally `{0,1}`-valued via `isOne`-wrapping, `datomDec_le_one/datomDec_eq_zero`, needed since `selectFn` is only well-behaved on a literal `0/1` condition): `atomUCode_succ/atomUEmpty_succ` (per-step unfoldings, mirroring `atomUPos_succ/atomUNeg_succ`); `atomUCodeState_congr` (the code-level analogue of `genAtom_congr/atomU_congr` — bit-sources agreeing on `deltaOf` below `n` give identical `(pos,neg,code)` triples, proved jointly since `atomUCode_succ`’s two `datomDec` checks read `atomUPos/atomUNeg`); `atomUEmpty_mono/atomUEmpty_zero_of_succ` (emptiness only propagates forward, via `genAtom_succ_subset`); `atomUCode_subset` (once-non-empty atoms shrink or stay equal depth-to-depth, mirroring `splitfst_subset/split_snd_subset` but unconditional since `UX_splitULeft/UX_splitURight` need no side hypotheses); and the headline `atomUCode_disjoint`, by induction on `n` exactly mirroring `atomU_invariant`’s disjointness case (Theorem88.lean ~lines 313–341): “agree below `n`, disagree at `n`” uses `atomUCodeState_congr` to identify the shared ancestor, then `splitU_disjoint` directly (no abstract `SplitSpec` needed, since `splitULeft/splitURight`’s disjointness is unconditional); “disagree below `n`” recurses and shrinks via `atomUCode_subset`. lake build green, zero sorry, #print axioms on `atomUCode_disjoint/atomUCode_mem` gives [`propext`, `Classical.choice`, `Quot.sound`] — the `Classical.choice` is pre-existing (from `datomDec`’s `RecDecidable` extraction, unchanged in kind from before this theorem), not new taint.

Theorem 8.8(b)(vii)(2)

- **Mathematical Target:** `YseqCode` — Scott’s Y_n , coded: a `Nat.Primrec` union, over the 2^n bit-sources $k < 2^n$ with bit `n` forced to 1 (i.e. $k + 2^n$ for $k < 2^n$), of `atomUCode P (n+1) (k+2^n)`, satisfying `UX (YseqCode P n) = Yseq`-analogue (the `Set`-level closed form Scott needs)
- **Lean File:** `Scott1980/Neighborhood/Theorem88d.lean`
- **Proof Notes:** Bit arithmetic first: `deltaOf_eq_testBit` identifies `deltaOf` with `Nat.testBit` outright, so `deltaOf_add_two_pow_of_lt/deltaOf_two_pow_add_self/deltaOf_mod_two_pow_of_lt` (how `deltaOf` reacts to $+2^n/2^n$) are direct transcriptions of `Nat.testBit_two_pow_add_gt/_eq/Nat.testBit_mod_two_pow`, no bespoke induction. **The fold (`yFoldStep/yFold`, noncomputable — inherits `atomUEmpty`’s classicality):** packs an accumulator (`found,code`) since junk atoms alias to `UX 0 = U.master` (`canonCode`’s degenerate-input fallback) and must be *skipped*, not unioned in, else the whole depth’s result would be corrupted to `U.master`; `found=0` means no genuine atom seen yet, `found=1` means `code` holds the running union (`unionUX`) of all genuine atoms seen so far — built as a single-packed-argument `Nat.Primrec.prec (primrec_yFold)`, mirroring `atomStep`’s own convention. **Nonemptiness (`exists_atomUEmpty_zero`):** mirrors `Theorem88a.lean`’s `Yidx_nonempty/self_mem_idxSet` transported through a new `encodeBits : (N→Bool)→N→N` helper (pure existence tool, never claimed `Primrec`) realizing a prescribed finite bit-prefix as an explicit witness bit-source, guaranteeing the fold’s `found` flag reaches 1 by $N=2^n$ (`yFold_two_pow_found`). `YseqCode P n := (yFold P n (2^n)).unpair.2`, `Nat.Primrec (primrec_YseqCode)` with closed form `mem_UX_YseqCode_iff : z ∈ UX (YseqCode P n) ↔ ∃ i<2^n, atomUEmpty P (n+1) (i+2^n)=0 ∧ z ∈ UX (atomUCode P (n+1) (i+2^n))`, by induction on the fold’s iteration count (`yFold_found_iff`, `yFold_mem_iff`). **Headline closed-form (`atomUCode_succ_true`, mirroring `splitfst_eq_inter_Yseq`):** for non-junk `k` with `deltaOf k n = true`, `UX (atomUCode P (n+1) k) = UX (atomUCode P n k) ∩ UX (YseqCode P n)`.

$\subseteq$ is `atomUCode_subset` (Part 1) meet `hcode_eq` (via `atomUCodeState_congr` identifying k with its canonical bit-source $k \cdot 2^n + 2^n$, which is exactly a term of `YseqCode`'s union). $\supseteq$: given z in both the depth- n atom and some genuine atom `atomUCode P (n+1) (i+2^n)` from `YseqCode`'s union, either $i+2^n$ agrees with k on all bits below $n+1$ — then `atomUCodeState_congr` forces the two depth- $(n+1)$ codes equal, done — or they disagree at some bit $< n$, in which case (vii)(1)'s `atomUCode_disjoint` forces $UX(\text{atomUCode } P \ n \ (i+2^n)) \cap UX(\text{atomUCode } P \ n \ k) = \emptyset$, contradicting z lying in both (`atomUCode_subset` pushes z down from depth $n+1$ to depth n first). `lake build green, zero sorry; #print axioms` on all three headline results gives [`propext`, `Classical.choice`, `Quot.sound`], matching the pre-existing baseline (`primrec_atomUCode/atomUCode_subset` already carry the identical footprint) — no new taint.

Theorem 8.8(b)(vii)(3)

- **Mathematical Target:** Assemble a fresh subsystem D'' via $n \mapsto UX \ (YseqCode \ P \ n)$ (or reuse `Theorem88a.lean`'s `DprimeU/domainIso` shape with `Yseq` replaced by this `YseqCode` closed form); prove $D \cong^D D''$ and $D'' \triangleleft U$; build a `ComputablePresentation` D'' with master index 0 and $X \ n := UX \ (YseqCode \ P \ n)$ (genuinely code-driven, unlike `Yidx`)
- **Lean File:** `Scott1980/Neighborhood/Theorem88e.lean`
- **Proof Notes:** New file (imports `Theorem88d.lean` + `Theorem88c.lean`), reindexing everything from `atomUCode/YseqCode` down to $Yc \ P \ n := UX \ (YseqCode \ P \ n)$. **Bridging step:** `hcoreIdxYc` (via a fresh `encodeBits : (N → Bool) → N → N` realizing any finite δ -prefix as some `deltaOf k`, plus `genAtom_Yc_empty_iff` from (vii)(2)'s closed form) proves $genAtom \ (idxSet \ (e \ P)) \ Set.univ \ \delta \ n = \emptyset \leftrightarrow genAtom \ (Yc \ P) \ U.master \ \delta \ n = \emptyset$ for arbitrary $\delta : N \rightarrow Bool$, letting `Theorem88.lean`'s abstract `transfer_dir/transfer_empty_iff` be re-instantiated locally (`transfer_dir_idxYc/transfer_empty_iff_idxYc/transfer_subset_iff_idxYc/transfer_inter_empty_iff_idxYc/transfer_double_subset_iff_idxYc/transfer_inter_eq_iff_idxYc`, `Yc-flavoured`) since the generic versions are private. `embed_subset_iff_code/embed_eq_iff_code` (`idxSet`-level) and their raw-level wrappers `embed_subset_iff_raw_code/embed_eq_iff_raw_code` (via `idxSet_subset_iff/idxSet_eq_iff`) complete the bridge. **Assembly then mirrors `Theorem88a.lean/Theorem88c.lean` verbatim** with $Yidx \ (e \ P) \mapsto Yc \ P : DprimeUCode \ (D'', mem \ Y := \exists n, Y = Yc \ P \ n)$, `DprimeUCode_subsystem` ($D'' \triangleleft U$), `toDprimeUCode/toDCode/domainIsoCode/isomorphic_DprimeUCode` ($D \cong^D D''$), and `DprimeUCodePresentation` (`ComputablePresentation` D'' , master index 0) — the two index relations (`DprimeUCode_interEq_computable/DprimeUCode_cons_computable`) and the intersection index (`(P0 \ P).inter`, reused verbatim) transfer through exactly as in `Theorem88c.lean`'s `DprimeUPresentation`, reusing `idxSet_inter_eq_iff_DAtom/DAtom_pair_recDecidable` (generic, stated for any `ComputablePresentation Q`) unchanged. `lake build green, zero sorry, zero warnings; #print axioms` on `isomorphic_DprimeUCode/DprimeUCode_subsystem/DprimeUCode_isEffectivelyGiven` gives [`propext`, `Classical.choice`, `Quot.sound`], **identical to** the classical Theorem 8.8(a)/(c) analogues (`isomorphic_DprimeU/DprimeU_subsystem/DprimeU_isEffectivelyGiven`) — no new taint; the `Nat.Primrec` core (`YseqCode`, `atomUCode`) underlying `Yc \ P` itself remains choice-free, per (vii)(1)/(vii)(2).

Theorem 8.8(b)(vii)(4)

- **Mathematical Target:** `IsComputableMap` for D'' 's `Subsystem.inj/Subsystem.proj` against U 's presentation — i.e. the actual headline claim of Theorem 8.8(b)(vii)
- **Lean File:** `Scott1980/Neighborhood/Theorem88f.lean`

- **Proof Notes:** New file (imports `Theorem88e.lean` + `Definition72.lean` + `Proposition612.lean`). Turned out not to need a bespoke `subsetUChar`-style decider at all: `Subsystem.inj_rel/Subsystem.proj_rel` unfold i/j 's relations to a `mem`-clause on each side *plus* a raw subset test, and every `mem`-clause is automatically true once both sides are read off their own presentations ($\langle n, \text{rfl} \rangle$ for D' via `DprimeUCodePresentation`, `U_mem_UX` for U), so both relations collapse to a **single already-generic fact**: `ComputablePresentation.incl_computable` (Definition 7.1, proved once for *any* presentation) applied to `UComputablePresentation`, reindexed along `YseqCode P` (`primrec_YseqCode`, Theorem 8.8(b)(vii)(2)) in one argument (i) or the other (j) via `RecDecidable.comp`. `DprimeUCode_inj_isComputableMap/DprimeUCode_proj_isComputableMap` package this (`decidable  $\implies$  r.e.`, `RecDecidable.re/REPred.of_iff`); `DprimeUCode_projectionPair_isComputable` bundles both directions. `lake build green`, zero sorry, zero warnings. `#print axioms` on all three gives [`propext`, `Classical.choice`, `Quot.sound`] — the `Classical.choice` is pre-existing, inherited from `YseqCode/atomUCode`'s own classicality (documented since (vii)(1)/(vii)(2)), not new taint.

Theorem 8.8(b)(viii)

- **Mathematical Target:** Part 8 of 8 — final assembly `theorem_8_8_b` (the computable-projection-pair analogue of `theorem_8_8_a`) plus documentation update
- **Lean File:** `Scott1980/Neighborhood/Theorem88g.lean`
- **Proof Notes:** Assembles Parts 7(3)/7(4) into the final statement, mirroring `theorem_8_8_a`'s shape but with D' additionally presented and the witnessing projection pair additionally `IsComputableMap`: `theorem_8_8_b {D} (P : ComputablePresentation D) : $\exists (D' : \text{NeighborhoodSystem } \mathbb{Q}) (P' : \text{ComputablePresentation } D') (h : D' \triangleleft U), (D \cong^D D') \wedge \text{IsComputableMap } P' \text{ UComputablePresentation } h.\text{inj} \wedge \text{IsComputableMap } \text{UComputablePresentation } P' h.\text{proj}$. No new mathematical content — a single existential witnessing (DprimeUCode P, DprimeUCodePresentation P, DprimeUCode_subsystem P, isomorphic_DprimeUCode P, DprimeUCode_inj_isComputableMap P, DprimeUCode_proj_isComputableMap P) (Theorem88e.lean/Theorem88f.lean, already built). lake build green, zero sorry, zero warnings (all pre-existing warnings in this build belong to earlier files, not this one). #print axioms theorem_8_8_b gives [propext, Classical.choice, Quot.sound], matching every ingredient's own audit — the Classical.choice is pre-existing (from YseqCode/atomUCode's classicality), not new taint. Theorem 8.8(b) is now fully Pass, all 8 parts (i)–(viii) done.`

Theorem 8.8(c)

- **Mathematical Target:** converse correspondence — a computable, finitary projection a of U yields an effectively given domain ($\{Y \in U \mid YaY\} \triangleleft U$ is effectively given)
- **Lean File:** — (umbrella; see sub-items 8.8(c)(i)–8.8(c)(vi) below for the per-part Lean files)
- **Proof Notes:** the naive reading of `arxiv.md`'s old one-line proof note (“ a 's graph r.e. + U -equality decidable $\implies \{Y \in U \mid YaY\}$ r.e. $\implies$ effectively given”) glosses over a real gap: `a.rel Xn Xn` being merely **r.e.**, not decidable, means the raw index set $S := \{n \mid X_n a X_n\}$ cannot be *filtered* into a `ComputablePresentation`'s enumeration directly — `interEq_computable/cons_computable` need genuinely **decidable** relations and a **primitive-recursive** `.inter`, and naive filtering by an r.e. predicate gives none of these. Broken into a 6-part plan (mirroring 8.8(b)'s style) tracked as sub-rows **8.8(c)(i)–8.8(c)(vi)**: (i) extract the decidable r.e.-witness relation for the diagonal $S(n) := a.\text{rel } X_n X_n$; (ii)

a `meetFold`-style primitive-recursive fold, *gated* by that witness relation at each list entry, whose accumulator is proved (by induction using `fixedNbhd_subsystem` `a`’s `inter_closed`) to **always** land back inside `S` — no unbounded search at any step, since the fold only ever combines two *already-witnessed* indices, never needs to find a fresh witness for a combined one; (iii) the induced enumeration `D_X : ℕ → Set α` covers `fixedNbhd a` exactly (`mem_X/surj`, the latter via a singleton-list code); (iv) `interEq_computable` (free, direct composition with `U`’s own decider through the primitive-recursive fold) and `cons_computable` (needs one real lemma: D-consistency of two fold-codes is equivalent to U-consistency of their underlying raw indices, via the subsystem relation both directions); (v) the `.inter` field itself, reusing `Recursive.lean`’s existing `appendListCode/primrec_appendListCode` (list concatenation) plus a “fold-from-a-valid-start distributes over ++” lemma for `inter_spec`; (vi) final assembly into `ComputablePresentation` (`fixedNbhd a`) and the headline `theorem_8_8_c`, wired into `Domain.lean`.

Theorem 8.8(c)(i)

- **Mathematical Target:** Part 1 of 6 — the diagonal fixed-point predicate `DiagFixed P a n := a.rel X_n X_n` (i.e. `(fixedNbhd a).mem X_n`, given `X_n` is always a U-neighbourhood) is recursively enumerable, given `a` is a computable map
- **Lean File:** `Scott1980/Neighborhood/Theorem88h.lean`
- **Proof Notes:** stated generally over any `V : NeighborhoodSystem α` and `P : ComputablePresentation V` (not just `U`; Theorem 8.8(c) itself will specialize `V := U, P := UComputablePresentation`). `DiagFixed P a n := a.rel (P.X n) (P.X n)`, shown $\leftrightarrow$ `(fixedNbhd a).mem (P.X n)` (`diagFixed_iff_fixedNbhd_mem`, one line via `P.mem_X`). `diagFixed_isREPred {ha : IsComputableMap P P a} : REPred (DiagFixed P a)`: restrict `IsComputableMap`’s `REPred` (`fun t => X_n a X_m`) (unfolding `IsComputableMap/REPred2` via a `have ... := ha` type ascription, mirroring `Theorem86c.lean`’s idiom) to the diagonal via `REPred.comp` against the primitive-recursive pairing `n ↦ Nat.pair n n` (built from the project’s own choice-free `primrec_id`, not `Mathlib`’s `Nat.Primrec.id` — confirmed by direct axiom check that the latter is `Classical.choice`-tainted upstream while the former is not). `diagFixed_exists_qChar` then unfolds `REPred`’s own definition (`p n ↔ ∃ i, q⟨i,n⟩` with `q` recursively decidable via a `{0,1}`-valued primitive-recursive `qChar`) to expose `qChar` directly: `DiagFixed P a n ↔ ∃ i, qChar⟨i,n⟩ = 1` — this is what Parts 2–4 gate their fold on. lake build green, zero sorry. `#print axioms` on all four declarations gives $\subseteq$ `{propext, Quot.sound}`, fully choice-free.

Theorem 8.8(c)(ii)

- **Mathematical Target:** Part 2 of 6 — a `qChar`-gated, `Nat.Primrec` list-fold (`myStep/myFoldCode`) whose accumulator is *always* a raw U-index satisfying `DiagFixed`, for any input list-code
- **Lean File:** `Scott1980/Neighborhood/Theorem88i.lean`
- **Proof Notes:** stated generally over any `V/P` (as with 8.8(c)(i)). Each list entry `e` codes a pair `⟨i,n⟩ = Nat.pair i n`: a candidate raw index `n` plus a *claimed* `qChar`-witness `i`. `myStep P qChar cons r e := selectFn (isOne(qChar e) * isOne(cons(pair r e.unpair.2))) (P.inter r e.unpair.2) r` — accumulator = raw index (no `(ok,idx)` pair needed, mirroring but simplifying `DAtomDecidable.lean`’s `meetStep/meetFold/meetFoldCode` shape): an invalid or inconsistent entry is simply *skipped* (no-op), rather than freezing the whole fold “not ok”. `myFold P qChar cons 1 := 1.foldl (myStep ...) P.masterIdx`; `myStepCode/myFoldCode` package this via the existing `foldCode` combinator, `Nat.Primrec` immediate from `primrec_foldCode` given `qChar/cons/P.inter` are primitive recursive

(`primrec_myStepCode/primrec_myFoldCode`). The mathematical content is the **invariant** `diagFixed_myFoldCode : DiagFixed P a (myFoldCode qChar cons c)` for every list-code `c` (given `a` computable, via `hqChar/hcons` hypotheses matching 8.8(c)(i)’s extracted witness and `P.cons_computable`): base case `DiagFixed P a P.masterIdx (diagFixed_masterIdx, via a.master_rel + P.masterIdx_spec)`; one-step preservation (`myStep_diagFixed_of_diagFixed`) either no-ops (trivial) or combines two already-`DiagFixed` raw indices via `P.inter` under a checked `V-consistency` witness, landing back in `DiagFixed` by `(fixedNbhd_subsystem a).inter_closed` plus `P.inter_spec`; folded across a list by a plain induction (`myFold_diagFixed_of_diagFixed/myFold_diagFixed`). **Pitfall hit:** composing `P.inter_primrec` (stated on `t.unpair.1/t.unpair.2`) against a re-paired argument via plain `.comp` (relying on definitional unification of the `unpair_pair` round-trip) caused a `whnf` pretty-printing timeout at elaboration; fixed by the standard idiom of composing then discharging the reindex explicitly via `.of_eq (fun w => by simp only [unpair_pair_fst, unpair_pair_snd])` instead of letting elaboration try to unify it definitionally. lake build green, zero sorry. `#print axioms` on every declaration gives $\subseteq \{\text{propext}, \text{Quot.sound}\}$, fully choice-free.

Theorem 8.8(c)(iii)

- **Mathematical Target:** Part 3 of 6 — the induced enumeration `D_X qChar cons c := P.X (myFoldCode qChar cons c)` is always a `fixedNbhd a`-neighbourhood (`mem_X`) and hits every one of them (`surj`)
- **Lean File:** `Scott1980/Neighborhood/Theorem88j.lean`
- **Proof Notes:** `D_X P qChar cons c := P.X (myFoldCode P qChar cons c)`. `D_X_mem` is Part 2’s invariant `diagFixed_myFoldCode` repackaged via `diagFixed_iff_fixedNbhd_mem` — one line. `D_X_surj`: given $Y \in \text{fixedNbhd } a$ (i.e. $V.\text{mem } Y \wedge a.\text{rel } Y Y$), `P.surj` produces a raw `V`-index `n0` with `P.X n0 = Y`; rewriting `Y`’s fixedness along `hn0` gives `DiagFixed P a n0`, and Part 1’s `hqChar` extracts a witness `i0` with `qChar⟨i0, n0⟩ = 1`. Feeding the **singleton list-code** `encodeList [Nat.pair i0 n0]` into the fold (`myFoldCode_eq + decodeList_encodeList + List.foldl_cons/_nil`) reduces to exactly one `myStep` from `P.masterIdx`: the `qChar`-gate passes by construction (`hi0` verbatim), and the `V-consistency` gate passes because `V.sub_master hYV : Y  $\subseteq$  V.master` makes `n0` itself a valid witness (`P.X n0  $\subseteq$  P.X P.masterIdx  $\cap$  P.X n0`, via `P.masterIdx_spec/hn0/Set.subset_inter`). The step therefore evaluates (via `selectFn_one`) to `P.inter P.masterIdx n0`, and `P.inter_spec + Set.inter_eq_right.mpr (V.sub_master hYV)` gives `P.X (P.inter P.masterIdx n0) = V.master  $\cap$  Y = Y`. lake build (whole project) green, zero sorry. `#print axioms` on `D_X/D_X_mem/D_X_surj` gives $\subseteq \{\text{propext}, \text{Quot.sound}\}$, fully choice-free.

Theorem 8.8(c)(iv)

- **Mathematical Target:** Part 4 of 6 — `D_X`’s `interEq/cons` relations are recursively decidable
- **Lean File:** `Scott1980/Neighborhood/Theorem88k.lean`
- **Proof Notes:** `D_X_interEq_computable` is free — `D_X c1  $\cap$  D_X c2 = D_X c3` unfolds *literally* to `Xn1  $\cap$  Xn2 = Xn3` for `ni := myFoldCode qChar cons ci`, so `RecDecidable3` follows by composing `P.interEq_computable` with the primitive-recursive triple-`myFoldCode` reindex (`primrec_myFoldCode`, Part 2) — no `a/DiagFixed` apparatus needed. `D_X_cons_iff` is the one genuine lemma: $\exists k, D_X k \subseteq D_X c_1 \cap D_X c_2$ (`D-consistency`)

is *equivalent* to $\exists k', X k' \subseteq X_{n1} \cap X_{n2}$ (plain V-consistency of the underlying raw indices) — $\implies$ is immediate since any D-witness $D_X k = X(\text{myFoldCode } k)$ is *already* a V-side witness (D_X 's codomain is literally $P.X$ of a raw index); $\impliedby$ uses Part 3's $D_X_of_diagFixed$: $P.\text{inter_spec}$ turns a V-consistency witness into $X(P.\text{inter } n_1 \ n_2) = X_{n1} \cap X_{n2}$, n_1, n_2 are both DiagFixed (Part 2's $\text{diagFixed_myFoldCode}$) so their meet is too ($\text{fixedNbhd_subsystem}$'s inter_closed), and $D_X_of_diagFixed$ produces the D-side witness code directly. $D_X_cons_computable$ then composes $P.\text{cons_computable}$ with the same primitive-recursive pair- myFoldCode reindex via this equivalence. lake build (whole project) green, zero sorry. #print axioms on all three gives $\subseteq \{\text{propext}, \text{Quot.sound}\}$, **fully choice-free** — but only after a pitfall fix: closing the final subset goal with le_of_eq (generic Preorder lemma) silently pulls in Classical.choice when specialized to $\text{Set } \alpha$'s order instance (confirmed by a standalone repro: $\text{le_of_eq} : s = t \rightarrow s \subseteq t$ audits with Classical.choice , while $h \triangleright \text{subset_rfl}$ for the identical goal does not); replaced with the $\triangleright$ -based idiom already used choice-free elsewhere in this codebase (Theorem88.lean 's $\text{hijk} := \text{heq} \triangleright \text{subset_rfl}$).

Theorem 8.8(c)(v)

- **Mathematical Target:** Part 5 of 6 — a primitive-recursive .inter field for D_X and its inter_spec
- **Lean File:** `Scott1980/Neighborhood/Theorem88l.lean`
- **Proof Notes:** $D_inter \ c_1 \ c_2 := \text{appendListCode } c_1 \ c_2$ (`Recursive.lean`'s Exercise 7.22 combinator, reused outright): correct because myFoldCode is a *left* fold from $P.\text{masterIdx}$, so List.foldl_append decomposes folding the concatenated list as folding c_2 's list *starting from* $\text{myFoldCode } c_1$ instead of from $P.\text{masterIdx}$ ($D_X_inter_eq$). The one genuine lemma, $\text{myFoldl_inter_of_le}$: refolding a list l from a start $n \subseteq r$ (in $P.X$) reproduces $X \ n \cap X(\text{fold of } l \text{ from } r)$, *provided* this is already known V-consistent at the fold's end. No $a/\text{DiagFixed}$ apparatus needed — purely structural about myStep 's gate. The subtlety: the gate $\text{cons}(\text{pair } r \ e.\text{unpair}.2)=1$ is *accumulator-dependent*, so refolding from a smaller start could in principle skip steps the original took; the induction (n, r advancing together) shows this never happens — a step failing from r also fails from the $\subseteq$ -smaller n (else n 's success would witness r 's success too, no extra hypothesis needed), and a step succeeding from r also succeeds from n , because the *global* end-of-fold witness is inherited by every intermediate accumulator via the fold's monotone-shrinking property ($\text{myStep_subset}/\text{myFoldl_subset}$: folding only ever shrinks $P.X$). $D_X_inter_spec$ then applies this with $n := \text{myFoldCode } c_1$, $r := P.\text{masterIdx}$ ($n \subseteq r$ via $V.\text{sub_master}$); the hypothesis is already V-side since D_X 's codomain literally *is* $P.X$ of a raw index. lake build (whole project) green, zero sorry. #print axioms on every declaration gives $\subseteq \{\text{propext}, \text{Quot.sound}\}$, **fully choice-free** — but only after an upstream pitfall fix in `Recursive.lean`: $\text{appendListCode_eq}/\text{primrec_appendListCode}$ (and their private helpers $\text{list_eq_of_getD}/\text{appendListTabFn_eq}/\text{primrec_appendListTabFn}$) were Classical.choice -tainted from a stray by_contra and two bare (non-only) $\text{simp } [\dots]$ calls that silently routed through a classically-proved default-simp-set lemma; fixed by replacing by_contra with a decidable Nat.lt_trichotomy case split and the bare simps with $\text{unfold} + \text{simp only } [\text{unpair_pair_fst}, \text{unpair_pair_snd}]$ (+ explicit $\text{by_cases}/\text{rw}$), with no change to any statement or def .

Theorem 8.8(c)(vi)

- **Mathematical Target:** Part 6 of 6 — final assembly: package Parts 1–5 into a genuine $\text{ComputablePresentation}$ ($\text{fixedNbhd } a$) and state `theorem_8_8_c`

- **Lean File:** `Scott1980/Neighborhood/Theorem88m.lean`
- **Proof Notes:** `fixedNbhd_isEffectivelyGiven {a} (hcomp : IsComputableMap P P a) : (fixedNbhd a).IsEffectivelyGiven`: obtains concrete witnesses for the two abstract functions Parts 2–5 were stated over — `qChar` from Part 1’s `diagFixed_exists_qChar hcomp`, and `cons` from `P.cons_computable` itself (unfolded/reindexed at `Nat.pair n m` via `unpair_pair_fst/unpair_pair_snd` into the exact `hcons` shape every part expects) — then packages Parts 1–5’s `D_X/D_inter` triple into a `ComputablePresentation (fixedNbhd a)` directly (`mem_X/surj/interEq_computable/cons_computable/inter/inter_primrec/inter_spec` from `D_X_mem/D_X_surj/D_X_interEq_computable/D_X_cons_computable/D_inter/D_inter_primrec/D_X_inter_spec` verbatim), with `masterIdx := 0 (D_X qChar cons 0 = P.X (myFoldCode ... 0) = P.X (myFold ... (decodeList 0)) = P.X (myFold ... []) = P.X P.masterIdx = V.master`, via `myFoldCode_eq/decodeList_zero/myFold_nil/P.masterIdx_spec`), wrapped in `Nonempty`. `theorem_8_8_c {a : ApproximableMap U U} (_hfin : IsFinitaryProjection a) (hcomp : IsComputableMap UComputablePresentation UComputablePresentation a) : (fixedNbhd a).IsEffectivelyGiven $\wedge$ fixedNbhd a $\triangleleft$ U is then a two-line pairing of fixedNbhd_isEffectivelyGiven hcomp with the unconditional fixedNbhd_subsystem a (Theorem 8.5); _hfin is carried (underscore-prefixed) to match Scott’s stated hypothesis on a but is genuinely unused — only hcomp drives the effectiveness argument, called out in the docstring rather than silently dropped. lake build (whole project) green, zero sorry, zero new warnings. Axiom audit, a genuine subtlety: #print axioms fixedNbhd_isEffectivelyGiven gives $\subseteq \{\text{proptext}, \text{Quot.sound}\}$ — fully choice-free, because both Exists-eliminations (diagFixed_exists_qChar, P.cons_computable) land in a Prop goal (IsEffectivelyGiven = Nonempty (ComputablePresen...)), which is legitimate choice-free Exists-elimination. But #print axioms theorem_8_8_c gives $\subseteq \{\text{proptext}, \text{Classical.choice}, \text{Quot.sound}\}$ — not new taint: U (Definition 8.7) already audits with Classical.choice for the documented upstream reason (Mathlib’s Rat order path), and the other two U-mentioning headline theorems, theorem_8_8_a/theorem_8_8_b, audit identically (confirmed directly) — any statement merely mentioning ApproximableMap U U/_ $\triangleleft$ U inherits U’s own footprint.`

Definition 8.9

- **Mathematical Target:** fixed computable projection pairs `i_+, j_+, i_×, j_×, i_→, j_→` for `U`, and combinators `a+b, a×b, a→b`
- **Lean File:** `Scott1980/Neighborhood/Theorem88n.lean`, `Scott1980/Neighborhood/Definition89.lean`
- **Proof Notes:** **The gap:** `theorem_8_8_b` (`Theorem88g.lean`) only gives a computable pair `D'  $\rightleftharpoons$  U` for an *isomorphic copy* `D'`, leaving `D  $\cong^D$  D'` a bare `Nonempty`; Definition 8.9 needs a direct pair `D  $\rightleftharpoons$  U` for `D :=  $\mathcal{U} + \mathcal{U} / \mathcal{U} \times \mathcal{U} / \mathcal{U} \rightarrow \mathcal{U}$` itself. **New general lemma** `theorem_8_8_b_strong (Theorem88n.lean)`: `domainIsoCode P’s iso D  $\cong^D$  DprimeUCode P` matches raw indices *literally* via the unconditional `embed_eq_iff_raw_code : e P i = e P j  $\leftrightarrow$   $\forall c P i = \forall c P j$` (`Theorem88e.lean`) along the primitive-recursive involution `eIdx P`; converting the `iso` to approximable maps via Theorem 2.7 (`ofIso`, choice-free) gives `isoInj/isoProj : D  $\rightleftharpoons$  DprimeUCode P` whose relations collapse to single reindexed `incl_computable` queries — `isoInj_rel_iff_incl : (isoInj P).rel (P.X a) ($\forall c P b$) $\leftrightarrow$ P.X a $\subseteq$ P.X (eIdx P b) (and symmetrically for isoProj), since n:=b/m:=eIdx P a is always a valid existential witness and any other witness is forced equal by embed_eq_iff_raw_code — hence computable (isoInj_isComputableMap/isoProj_isComputableMap). Composing with DprimeUCode_subsystem P’s pair (Theorem88f.lean, computable) gives theorem_8_8_b_strong : $\exists i j, j.comp i = idMap D \wedge i.comp j \leq idMap U \wedge IsComputableMap P UComputablePresentation i \wedge IsComputableMap UComputablePresentation P j$ —`

reasoning choice-free, statement inherits $\mathcal{U}$'s `Classical.choice` (confirmed identical footprint to `theorem_8_8_a/b/c`). **Definition 8.9 itself** (`Definition89.lean`): `sumUU_isEffectivelyGiven/prodUU_isEffectivelyGiven/funSpaceUU_isEffectivelyGiven` (Theorem 7.4/7.5 applied twice to $\mathcal{U}$'s presentation); the six fixed maps `iPlus/jPlus`, `iTimes/jTimes`, `iArrow/jArrow` (+ four laws each) are `theorem_8_8_b_strong` applied to a fixed presentation of $\mathcal{U} + \mathcal{U} / \mathcal{U} \times \mathcal{U} / \mathcal{U} \rightarrow \mathcal{U}$, extracted via `.choose/.choose_spec` — Scott's "let ... be fixed" is exactly this arbitrary choice out of a non-unique existential, same pattern as $\mathcal{U}$ itself, no *marginal* taint. The three combinators are a direct transcription of Scott's formulas with no new math: `sumComb a b := cond ∘ ⟨which, i+ ∘ in0 ∘ a ∘ out0, i+ ∘ in1 ∘ b ∘ out1⟩ ∘ j+` (`cond/whichMap` Ex. 3.26, `inMap0/1/outMap0/1` Ex. 3.18/3.19, paired); `prodComb a b := i× ∘ ⟨a ∘ proj0, b ∘ proj1⟩ ∘ j×`; `arrowComb a b := i→ ∘ (λf. b ∘ f ∘ a) ∘ j→` with `λf. b ∘ f ∘ a := curry (b ∘ eval ∘ (id ×m a))` (`curry/evalMap/prodMap, FunctionSpace.1`). Both files: `lake build` (whole project, 3153 jobs) green, zero sorry; `#print axioms` on `sumComb/prodComb/arrowComb`/the six maps all give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, the same inherited $\mathcal{U}$ -footprint. **Not attempted:** Proposition 8.10 (separate item) and Exercise 8.17's explicit formulas.

Proposition 8.10(a)

- **Mathematical Target:** if $a, b: \mathcal{U} \rightarrow \mathcal{U}$ are projections, then so are $a+b$, $a \times b$, $a \rightarrow b$
- **Lean File:** `Scott1980/Neighborhood/Proposition810.lean`
- **Proof Notes:** Four generic element-level lemmas open the file: `toElementMap_of_comp_eq_idMap (j ∘ i = I_D ⇒ j(i(v)) = v)`, `toElementMap_le_of_comp_le_idMap (i ∘ j ≤ I_E ⇒ i(j(x)) ≤ x)`, `toElementMap_le_self_of_le_idMap (a ≤ I_E ⇒ a(x) ≤ x)`, `toElementMap_idem_of_isRetraction (a ∘ a = a ⇒ a(a(x)) = a(x))`. `×`: `prodComb a b = iTimes ∘ (prodMap a b) ∘ jTimes` *literally* (Exercise 3.19's product-functor combinator, `rfl`); both closure facts reduce to `pair_le_pair_iff/toElementMap_prodMap/toElementMap_mono` plus the generic lemmas. `→`: `lamComb a b`, transported through `funSpaceEquiv` (Theorem 3.10), is exactly `f → b ∘ f ∘ a` (`toApproxMap_toElementMap_lamComb`, chaining `toElementMap_curry_apply/toElementMap_prodMap_pair/evalMap_apply`); reduces to the same `×`-style algebra transported back through `toApproxMap`. **(no bridge to sumMap, since it isn't literally cond/which-built):** `toElementMap_sumComb_mem` unfolds `sumComb` via `toElementMap_comp/toElementMap` paired down to `cond_toElementMap_mem` (Ex. 3.26); three value-formula lemmas (`toElementMap_sumComb_of_left/right/neither`) case-split on `sum_element_trichotomy`, using `which_mem_zero/one` + the disjointness fact `not_sum_reaches_both (inj0_inter_inj1/not_sum_mem_empty)` to rule out the wrong guard, and `inj0/1_ne_sumMaster` to rule out both guards in the "neither" case. Idempotence's left/right cases re-enter the same case via the *unconditional* round-trip `outMap0_comp_inMap0 = idMap` plus new `inMap0_toElementMap_reaches_left/inMap1_toElementMap_reaches_right` (witnessed by the master neighbourhood); the "neither" case needs `jPlus_bot_eq_bot`, an instance of a clean general fact `toElementMap_bot_eq_bot_of_comp_eq_idMap` (any `j ∘ i = I_D` sends `E.bot` to `D.bot`, via `D.bot ≤ i(D.bot)` monotone through `j` plus antisymmetry with `bot_le` — no disjointness needed). Assembled: `isProjection_sumComb/isProjection_prodComb/isProjection_arrowComb/isProjection_combinators`. Zero sorry; `lake build` (3010 jobs) green, no warnings; `#print axioms` on all four headline theorems gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ the same inherited $\mathcal{U}$ -footprint, nothing new.

Proposition 8.10(b)

- **Mathematical Target:** if a, b are finitary, then so are $a+b$, $a \times b$, $a \rightarrow b$, with $D_{\{a+b\}} \cong D_a + D_b$, $D_{\{a \times b\}} \cong D_a \times D_b$, $D_{\{a \rightarrow b\}} \cong (D_a \rightarrow D_b)$

- **Lean File:** Scott1980/Neighborhood/Proposition810b.lean

- **Proof Notes: Setup:** for a finitary projection a , Theorem 8.6's `sub_eq_self_of_isFinitaryProjection` gives $a = i_a \circ j_a$ for the *concrete* subsystem pair $i_a, j_a : D_a \rightleftharpoons \mathcal{U}$ ($D_a := \text{fixedNbhd } a$, Theorem 8.5), replacing the abstract `IsFinitary` witness with something to compute against. **Generic tool `elementIsoOfProjectionPair`** (Proposition 8.2's `elementIso`, generalized off the literal $D \triangleleft E$ requirement to *any* approximable pair $i:D \rightarrow E, j:E \rightarrow D$ with $j \circ i = I_D$, no shared token type needed, and $g := i \circ j$): gives $D.\text{Element} \simeq_o \text{Fix}(g)$ directly — verbatim `Subsystem.elementIso`'s proof. For each combinator $* \in \{+, \times, \rightarrow\}$, build a *new* pair $I:D_a * D_b \rightarrow \mathcal{U}, J:\mathcal{U} \rightarrow D_a * D_b$ by transporting Definition 8.9's fixed maps through $*$'s functorial action on i_a, j_a, i_b, j_b ; the two composite laws $J \circ I = \text{idMap}$ and $I \circ J = a * b$ (proved algebraically from the functor laws plus $i_a \circ j_a = a / i_b \circ j_b = b$) feed `elementIsoOfProjectionPair` for $D_{\{a*b\}} \cong D_a * D_b$ and `IsFinitary(a*b)` in one shot; `IsProjection(a*b)` is Proposition 8.10(a). $\times$ (**cleanest**): `prodComb` is literally $i\text{Times} \circ (\text{prodMap} \cdot) \circ j\text{Times}$, so $I\text{ProdComb} := i\text{Times} \circ \text{prodMap}(i_a, i_b) / J\text{ProdComb} := \text{prodMap}(j_a, j_b) \circ j\text{Times}$ close via Ex. 3.19/3.20's `prodMap_id/prodMap_comp` directly. $+$ (**new `sumMap` infrastructure, ~200 lines**): unlike $\times$, `sumComb` is *not* literally $i\text{Plus} \circ \text{sumMap} \circ j\text{Plus}$ by `rfl` (Definition 8.9 builds it via `cond/whichMap` instead) — proved *elementwise equal* instead (`sumComb_eq_iPlus_sumMap_jPlus`, case-splitting on `sum_element_trichotomy` against Proposition810.lean's own `toElementMap_sumComb_of_left/right/neither` formulas, matched against new elementwise formulas for `sumMap` itself: `sumMap_reaches_left/right`, `toElementMap_sumMap_inMap0/1` (via the existing `outMap0_comp_sumMap_comp_inMap0` identity plus round-trips), `toElementMap_sumMap_of_left/right`, `sumMap_bot`, and `reaches_neither_iff_eq_bot`); the bottom case needs a new general fact `toElementMap_bot_eq_bot_of_comp_le_idMap` ($i \circ j \leq I_E \implies i(D.\text{bot}) = E.\text{bot}$, via $i(D.\text{bot}) \leq i(j(E.\text{bot})) \leq E.\text{bot}$ plus `bot_le`). This bridge in hand, `sumMap_id/sumMap_comp` (proved via the *same* elementwise case-split, reusing the formulas — genuinely a functor, $f+g$ on raw `sum`-neighbourhoods) give `IsumComb/JsumComb` closing exactly like $\times$. $\rightarrow$ (**new `expMap` bifunctor, generalizing `lamComb`**): `expMap h k : (D_0 \rightarrow D_1) \rightarrow (D_0' \rightarrow D_1')` for $h:D_0' \rightarrow D_0$ (contravariant), $k:D_1 \rightarrow D_1'$ (covariant), built exactly as `lamComb` (`curry(k \circ eval \circ (id \times_m h))` but for arbitrary systems (`lamComb a b = expMap a b` on the nose, `rfl`); `toApproxMap_toElementMap_expMap` ($f \mapsto k \circ f \circ h$ transported through `funSpaceEquiv`) is Proposition810.lean's `toApproxMap_toElementMap_lamComb` proof verbatim, generalized; `expMap_id/expMap_comp` (contravariant composition law) follow by transporting through `funSpaceEquiv`'s injectivity plus `comp_assoc` bookkeeping. `IArrowComb := iArrow \circ expMap(j_a, i_b) / JArrowComb := expMap(a, j_b) \circ jArrow` then close identically to $\times/+$. Assembled: `finitaryProjection_sumComb/finitaryProjection_arrowComb/finitaryProjection_combinators`, plus the three explicit isomorphisms `sumComb_elementIso/prodComb_elementIso/arrowComb_elementIso`. `lake build` (whole project, 3155 jobs) green, zero sorry; `#print axioms` on all seven headline results gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, the same inherited U-footprint, nothing new.

Exercise 8.11

- **Mathematical Target:** $R = \{[0, r) \mid r \in \mathbb{Q}, 0 < r \leq 1\}$; $[0, r) \sqcup [0, s)$ iff $r < s$ or $r = s = 1$ is approximable, a is a projection whose fixed-point set $\leftrightarrow [0, 1] \subseteq \mathbb{R}$ (Dedekind cuts), and a is NOT finitary
- **Lean File:** Scott1980/Neighborhood/Exercise811.lean
- **Proof Notes:** $R := \text{ofNestedOrDisjoint-style chain system } \{[0, r) \mid 0 < r \leq 1\} \text{ over } \mathbb{Q}$ (nested by r , so no disjoint case ever fires). $a\text{Rel } X \ Y := \exists r \ s, X = [0, r), Y = [0, s), (r < s \vee r = s = 1)$;

a : `ApproximableMap R R` from `aRel`, with `inter_right/mono` reduced to endpoint arithmetic via helper lemmas `Ico0_inj` (injectivity of $r \mapsto [0, r]$), `Ico0_le_of_subset`, `Ico0_inter ([0, r] ∩ [0, s] = [0, min r s])`, `aRel_combine`. `isRetraction_a/isProjection_a`: direct endpoint unwinding (retraction’s $\exists$ -witness for $r < t$ is `exists_between`; projection is `aRel_le`). **Fixed-point correspondence**: `R.Elements` are characterized by “up-set” predicates $U: \mathbb{Q} \rightarrow \text{Prop}$ on $(0, 1]$ (`Element.ext_U, mkElement`); Scott’s Dedekind cut for $t \in [0, 1]$ is $\text{cutU } t \ r := r \leq 1 \wedge (1 - t < r \vee r = 1)$ (`cutElt t`), shown to be `a`-fixed (`toElementMap_cutElt`, using density `exists_rat_btwn` for the “openness” direction) and to satisfy $\subseteq$ matches $\leq$ (`cutElt_le_iff`, i.e. Scott’s hint verbatim). Surjectivity: any fixed x ’s canonical cut point is $\text{cutPoint } x := 1 - \text{sInf } (\text{cutS } x)$ where $\text{cutS } x := \{(r: \mathbb{R}) \mid x.\text{mem}[0, r]\}$ (`cutElt_cutPoint`, using `exists_lt_of_csInf_lt` for the reverse direction); antisymmetry of `cutElt_le_iff` gives injectivity (`cutElt_injective`). Packaged as `fixOrderIso : Fix(a)  $\simeq_o$  Set.Icc (0:  $\mathbb{R}$ ) 1` (noncomputable, via `sInf`). **Non-finitarity**: `not_isCompactElt_pos` shows $\text{no } g\langle t, _, _ \rangle$ with $t > 0$ is `IsCompactElt`, for *any* $g : \text{Set.Icc}(0: \mathbb{R}) 1 \simeq_o \text{F.Element}$ — the directed family $\{g\langle s, _, _ \rangle \mid 0 \leq s < t\}$ has sup exactly $g\langle t, _, _ \rangle$ (`isLUB_Ico` transported via `OrderIso.isLUB_image'`, matched against `iSupDirected`’s own `le_iSupDirected/iSupDirected_le` LUB-characterization by `IsLUB.unique`), yet $g\langle t, _, _ \rangle$ is strictly above every member — exactly Scott’s hint (“aside from $\perp$, no finite elements”). `not_isFinitary_a`: assuming `IsFinitary a` gives $e: \text{Fix}(a) \simeq_o \text{F.Element}$; compose $g := \text{fixOrderIso.symm.trans } e$; every principal approximant of $x := g\langle 1, _, _ \rangle$ is compact (`principal_isCompactElt`) hence (by `not_isCompactElt_pos`’s contrapositive) equals $g\langle 0, _, _ \rangle$; algebraicity (`eq_iSupDirected_principal x`) then forces $x = g\langle 0, _, _ \rangle$, contradicting injectivity of g at $1 \neq 0$. Zero sorry; lake build (whole project, 3156 jobs) green; `#print axioms on a/isRetraction_a/isProjection_a/fixOrderIso/not_isFinitary_a` all give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (`Classical.choice` inherited from Mathlib’s $\mathbb{Q}/\mathbb{R}$ order instances, same as `Definition87.lean`’s $\mathcal{U}$; no new choice usage beyond that).

Exercise 8.12

- **Mathematical Target**: Generalize $2X+1$ to $2^k X + \ell$ ($\ell < 2^k$); V = non-empty finite unions of $2^k \mathbb{N} + \ell$; show $U \cong V$ effectively, another presentation of U
- **Lean File**: `Scott1980/Neighborhood/Exercise812.lean`; umbrella — see sub-rows **8.12(a)–8.12(g)** below for the full breakdown
- **Proof Notes**: Broken into a **7-part plan** (mirroring how Theorem 8.8 was split into 15 files/ $\sim 4,470$ lines across (a)/(b)/(c)), tracked as sub-rows **8.12(a)–8.12(g)**, **all now Pass**: V ’s construction/closure/faithfulness (a), its `ComputablePresentation` (b), the general two-sided back-and-forth lemma (c), its effective refinement (d), U/V each satisfying the extension property relative to the other (e)/(f), and the final assembly (g) — zero sorry project-wide. **Why $U \cong V$ is hard (not just tedious)**: order isos preserve compactness, and `compact = principal` (general facts, `Theorem85.lean`), so $U \cong V$ would force `principal_U([1/3, 2/3])` (a genuine compact U -element, non-dyadic endpoints) to correspond to a *single* V -neighbourhood — impossible, since no finite union of $2^k \mathbb{N} + \ell$ equals $[1/3, 2/3)$ exactly. So “restrict a U -filter to its dyadic trace” is provably the wrong map, not just hard to compute. The isomorphism is instead built via a genuinely different technique: a **computable back-and-forth** matching of the full (richly-overlapping, atomless — `U_no_minimal/V_no_minimal`) neighbourhood posets, analogous to the classical fact that countable atomless dense structures of the same signature are isomorphic — see sub-rows for full detail. **Final result**: `effectiveIso812_UV : EffectiveIso UComputablePresentation VComputablePresentation` (`Exercise812g4.lean`).

Exercise 8.12(a)

- **Mathematical Target:** Part 1 of 7 — define V : the neighbourhood system over $\mathbb{N}$ of non-empty finite unions of $2^k \mathbb{N} + \ell$ ($\ell < 2^k$), with its basic structural properties
- **Lean File:** `Scott1980/Neighborhood/Exercise812.lean`
- **Proof Notes:** $\text{affine } k \ell := \{n \mid n \% 2^k = \ell\}$ (Scott’s $2^k \mathbb{N} + \ell$, auto- $\emptyset$ for $\ell \geq 2^k$). Bookkeeping-free encoding $\text{levelSet } k m := \{n \mid m.\text{testBit}(n \% 2^k)\}$ (a single bitmask replaces `Definition87.lean`’s `List`, since residue classes at a fixed level partition $\mathbb{N}$, unlike arbitrary rational intervals). $\text{upsample } k k' m$ re-expresses a level- k mask at finer level k' via $\text{Nat.equivBitIndices}$ ($\mathbb{N} \simeq \text{Finset } \mathbb{N}$ bit-index bijection), giving levelSet_upsample ; levelSet_inter (upsample-both-then- $\&\&\&$) shows closure under intersection **unconditionally** (mirrors `Example78.lean`’s PN , unlike U which needs a consistency hypothesis). $V : \text{NeighborhoodSystem } \mathbb{N}$ from these. $V_no_minimal$ (Scott’s Def-8.7 remark transplanted): refine one level finer so every witnessing bit ℓ_0 doubles into $(\ell_0, \ell_0 + 2^k)$, peel off one copy, the twin guarantees the “rest” is non-empty. $V_mem_iff_finiteUnion$ (faithfulness, mirrors $U_mem_iff_scott$): via V_union_mem/V_iUnion_mem (mirrors U_union_mem/U_iUnion_mem) reassembling Scott’s literal finite unions from levelSet . Zero sorry; axiom footprint $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, confirmed an upstream Mathlib $\mathbb{N}/\text{Finset}/\text{Set}$ API artifact (not a choice made in this file — see the file’s own docstring).

Exercise 8.12(b)

- **Mathematical Target:** Part 2 of 7 — V ’s effective presentation (`ComputablePresentation V`), mirroring `UComputablePresentation.lean`
- **Lean File:** `Scott1980/Neighborhood/LevelSetPrimrec.lean`
- **Proof Notes:** built the missing `Nat.Primrec` bit-manipulation infrastructure from scratch (choice-free base combinators only, no Mathlib `Primrec/Nat.testBit/Nat.land`): `myDivPow2/myTestBit` (iterate “halve” via `Nat.Primrec.prec`, matching `Nat.testBit_eq_decide_div_mod_eq`), `myLand` (bitwise AND, a bit-for-bit mirror of `Recursive.lean`’s `myLor`), and `myUpsample` — the key missing piece — realized *arithmetically*, not bit-by-bit: one level-step duplicates a mask’s low 2^k bits into a second copy shifted up by 2^k positions (`myUpsampleStep k m := 2^(2^k) * m + m` with `m' := myModPow2 m (2^k)`; truncating first, via `Nat.testBit_two_pow_mul_add`, is what makes this correct regardless of the input’s “junk” high bits), iterated $k' - k$ times via `Nat.Primrec.prec` jointly tracking $(\text{level}, \text{mask})$ (mirrors `myLor`’s joint-state iteration), with a final `myModPow2` re-truncation so the output is *always* bounded (`myUpsample_lt`) even when $k=k'$. Non-emptiness (`levelSet_nonempty_iff`’s bounded $\exists$) decides via the existing `bExistsFn` combinator with `myTestBit` as body — no new quantifier infrastructure needed. Canonicalization (`canonIdx/VX`) mirrors `UComputablePresentation.lean`’s `canonCode` but is simpler (a (k, m) pair is always syntactically well-formed, only possibly empty): keep `n=pair k m` unchanged if non-empty, else fall back to the master code `pair 0 1`. Scott’s two relations reduce to bitmask arithmetic: intersection is `myUpsample-both-then-myLand` at level $\max k_1 k_2$ (`levelSet_myInter`, mirroring `levelSet_inter`); equality of two `levelSets` reduces to equality of their `myUpsample`-normalized (hence bounded, hence *unique*) masks (`levelSet_inj_of_lt`, `levelSet_eq_iff_myUpsample_eq`), decided by `RecDecidable.natEq`; consistency reduces to non-emptiness of the raw intersection (`Vcons_iff_nonempty_inter`, mirroring `U_cons_iff_nonempty_inter`). Zero sorry; axiom footprint $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (same inherited $\mathbb{N}/\text{Finset}/\text{Set}$ API artifact as 8.12(a), not a new choice made in this file).

Exercise 8.12(c)

- **Mathematical Target:** Part 3 of 7 — new general (non-effective) lemma: two countable, atomless neighbourhood systems D_0, D_1 , each satisfying a mutual one-step “extension”/splitting property relative to the other, are order-isomorphic ($D_0.\text{Element} \simeq_o D_1.\text{Element}$)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean` (in progress); umbrella — see sub-rows **8.12(c)(i)–8.12(c)(vii)** below for the full breakdown (both what’s done and what’s deferred), mirroring how Theorem 8.8(b)/(c) were split
- **Proof Notes:** the genuinely new piece of abstract theory this exercise needs, broken into a 7-part plan tracked as sub-rows **8.12(c)(i)–8.12(c)(vii)**, **all now Pass:** Boolean-closure prerequisites (i), generic hypotheses + free Boolean-atom infrastructure (ii), `Theorem88.lean`’s splitting lemma generalized to an abstract atomless target (iii), the interleaved two-sided atom construction + its core invariant (iv), pairwise disjointness of that construction across sign sequences (v, itself split into 5 sub-sub-parts — see 8.12(c)(v)’s own sub-rows), bidirectional transfer lemmas + the genuine-neighbourhood glue (vi, 7 sub-parts), and the final `DomainIso D0 D1` assembly (vii, 6 sub-parts — `domainIso812c/isomorphic_812c`). **Key structural discovery driving (i)–(v):** unlike Theorem 8.8(a)’s one-sided `exists_split/atomU` (where only the U-side is ever kept a genuine neighbourhood-or- $\emptyset$, via `U_no_minimal`’s choice-driven splitting, while the D-side atom is an uninterpreted Boolean combination that need never lie in D), a genuine *two-sided* isomorphism needs **both** sides to remain neighbourhood-or- $\emptyset$ at every step, including immediately after being intersected/subtracted by the *other* side’s enumerated term. This is resolved by discovering U and V are both **Boolean-closed** (closed under set-difference, not just consistent intersection), which makes Boolean atoms automatically `mem-or- $\emptyset$` by direct computation, with no choice-driven invariant-tracking needed for that half of the work. **Key structural discovery driving (vi)–(vii):** bidirectional transfer between X/Y (the input enumerations) and `XPseq/YPseq` (the atom construction’s induced enumerations) needs both same-family facts (direct `transfer_dir/transfer*_combined` specializations) and two genuinely new *cross-family* lemmas not visible from `Theorem88a.lean`’s single-enumeration precedent — `X_subset_YPseq_iff_XPseq_subset_Y/YPseq_subset_X_iff_Y_subset_XPseq` (cross-parity order) and `XPseq_eq_Y_iff_X_eq_YPseq` (cross-parity equality, `embed_eq_iff`’s two-family generalization) — needed because `toD1/toD0`’s `up_mem` cases must rename a witness discovered in *one* family’s covering enumeration back into the *other* family’s coordinates. See sub-rows for full detail.

Exercise 8.12(c)(i)

- **Mathematical Target:** Part 1 of 7 — U and V are Boolean-closed (closed under set-difference, not just consistent intersection) and Positive (Exercise 1.19)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `U_diff_mem` is a two-line corollary of the *already-existing* `IntervalPrimrec.lean`’s `diffLists/presentedIntervals_diffLists` (built long ago for the computable-presentation work, never previously used for this purpose): only non-emptiness of the raw difference can obstruct `U.mem`, since presentability and $\subseteq [0,1)$ transfer automatically. `V_diff_mem` needs one new bitmask identity: `testBit_xor_and_self` shows $a \wedge \neg b$ (`a &&& b`) is bitwise “a and not b” (since `a &&& b` is always a submask of `a`, XOR-ing it out just clears exactly those shared bits), giving `levelSet_diff` (mirroring `levelSet_inter`’s own `upsample-then-&&&` formula) and hence `V_diff_mem`. Also proved: `U_isPositive/V_isPositive` (both systems’ raw intersections are unconditionally presentable, so `mem(X $\cap$ Y)`

$\leftrightarrow (X \cap Y).Nonempty$ — free from `combineIntervals/levelSet_inter`), and `U_noMinimal/V_noMinimal` repackaging the existing `U_no_minimal/V_no_minimal` into the generic `NoMinimal` shape (below).

Exercise 8.12(c)(ii)

- **Mathematical Target:** Part 2 of 7 — generic `NoMinimal/DiffClosed` hypotheses, and the payoff: finite Boolean combinations (`Theorem88.lean`’s `genAtom`) are automatically `mem-or- $\emptyset$` , no choice needed
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `NeighborhoodSystem.NoMinimal/.DiffClosed` generalize `U_no_minimal/V_no_minimal/(i)`’s difference-closure as abstract hypotheses — `NoMinimal` phrased with explicit `Y.Nonempty/Z.Nonempty` clauses rather than `U_no_minimal`’s `Y $\neq$ X/Z $\neq$ X`, since an abstract `D.mem` need not itself carry nonemptiness the way `U.mem/V.mem` do (logically equivalent given `Y $\cap$ Z= $\emptyset$ /Y $\cup$ Z=X`, but directly what `exists_split'` needs). The headline payoff `genAtom_mem_or_empty`: for a Positive, difference-closed `D` with an enumeration `Z` of `D`-neighbourhoods, `genAtom Z D.master  $\delta$  n` (a finite Boolean combination of `Z`’s terms *and their complements*) is `mem-or- $\emptyset$` for *every* `n,  $\delta$` — a direct 2-case induction (intersect-with-a-neighbourhood via Positivity, subtract-a-neighbourhood via difference-closure), needing no choice-driven splitting to keep the atom “in the family” (unlike `Theorem 8.8(a)`’s `atomU_invariant`, which needed exactly such splitting since `D` there is *not* assumed Boolean-closed). One-step building blocks `inter_mem_or_empty/diff_mem_or_empty` extracted for reuse in (iv)’s two-sided construction.

Exercise 8.12(c)(iii)

- **Mathematical Target:** Part 3 of 7 — generalize `Theorem88.lean`’s `exists_split/SplitSpec/splitCh` from the hardcoded target `U` to an abstract atomless system `E`
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `exists_split'/SplitSpec'/splitChoice'` are verbatim proof transcriptions of `Theorem88.lean`’s originals with `U/U.mem/U_no_minimal` replaced by an abstract `E/E.mem/hEnomin : E.NoMinimal`, so the same lemma can later be instantiated with `E:=D1` (splitting `D1`’s side against a `D0`-enumerated target) or `E:=D0` (symmetrically) — the one place genuine `Classical.choice` enters, exactly as in `Theorem 8.8(a)`.

Exercise 8.12(c)(iv)

- **Mathematical Target:** Part 4 of 7 — the interleaved two-sided atom construction `atomPair` and its core invariant (matched emptiness, `mem-or- $\emptyset$` on both sides at every depth)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** Fix `D0, D1` (Positive, difference-closed, atomless) with enumerations `X, Y` covering their neighbourhoods. `atomPair` tracks a matched pair `(A, B):Set  $\alpha$   $\times$  Set  $\beta$` , refined by *two* sub-steps per depth `n`: an **X-sub-step** (test `A` against `X n` directly — free by (ii)’s Boolean-closure — and correspondingly split `B` via `exists_split'` with `E:=D1`, exactly `Theorem 8.8(a)`’s `exists_split`), then a **Y-sub-step** (symmetrically: test the *new* `B` against `Y n` directly, split the *new* `A` via `exists_split'` with `E:=D0`). A sign sequence `$\delta:\mathbb{N} \rightarrow \text{Bool} \times \text{Bool}$` selects the `+/-` branch at each sub-step. `atomPair_invariant` proves, by one induction alternating the two kinds of step, that at every depth and for every `$\delta$` :

(a) the pair has matching emptiness, (b)/(c) each side is `mem-or- $\emptyset$` — using (ii)’s `inter_mem_or_empty/diff_mem_or_empty` for the “tested” side (free) and (iii)’s `splitChoice'_isSplitSpec` for the “split” side (choice), alternating roles between the two sub-steps.

Exercise 8.12(c)(v)

- **Mathematical Target:** Part 5 of 7 — pairwise disjointness of `atomPair` across sign sequences disagreeing before depth `n`, on *both* sides simultaneously (the two-sided analogue of `Theorem88.lean`’s `atomU_invariant`’s third clause)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean` (umbrella; see sub-items 8.12(c)(v)(1)–8.12(c)(v)(7) below for the per-part breakdown)
- **Proof Notes:** needed so that a `Yseq`-style union over depth-`n` atoms recovers a well-defined, non-overlapping decomposition on *both* the D_0 - and D_1 -sides at once (unlike `Theorem 8.8(a)`, where only the U -side ever needed this). Broken into 5 sub-sub-parts, mirroring how `Theorem 8.8(b)(vii)` was split into (1)–(4): a generic single-sub-step abstraction (1), its two named instances `xStep/yStep` with their subset/disjointness lemmas (2), the glue connecting `atomPair`’s own recursion to that decomposition (3), overall monotonicity (4), and the headline disjointness induction itself (5).

Exercise 8.12(c)(v)(1)

- **Mathematical Target:** the generic single-sub-step abstraction `xyStep split A B Xn b` — “intersect/subtract `A` by `Xn` directly per sign `b`, and correspondingly split `B` via an abstract `split` function” as one ordinary (non-recursive) function — plus its local pairwise-disjointness fact `xyStep_disjoint_of_ne` (two applications at *different* sign bits land in disjoint sets, on *both* output components)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** two elementary, fully generic set-theory facts drive it: `if_swap_disjoint` (if $P \cap Q = \emptyset$ then if `b` then `P` else `Q` and if `b'` then `P` else `Q` are disjoint whenever $b \neq b'$, by case-splitting both booleans) and `inter_diff_self_eq_empty` ($(P \cap Q) \cap (P \setminus Q) = \emptyset$, immediate by `ext/tauto`). The “direct” output’s disjointness is `if_swap_disjoint` applied to the latter; the “split” output’s disjointness is `if_swap_disjoint` applied to `SplitSpec`’s own $I \cap J = \emptyset$ clause (8.12(c)(iii)). Placed *before* `xStep/yStep` and fully generic ($\{\alpha \ \gamma : \text{Type}^*\}$, abstract `split`), so it is reusable verbatim for both named sub-steps.

Exercise 8.12(c)(v)(2)

- **Mathematical Target:** the two named sub-steps of `atomPair` as instances of (v)(1)’s `xyStep`: `xStep` (split D_1 ’s side via `splitChoice'`, directly refine D_0 ’s side) and `yStep` (symmetric, with a `.swap` to restore (α, β) -side ordering) — together with their subset lemmas (`xStep_fst_subset/xStep_snd_subset/yStep_fst_subset/yStep_snd_subset`) and disjointness corollaries (`xStep_disjoint_of_ne/yStep_disjoint_of_ne`, direct instances of (v)(1)’s `xyStep_disjoint_of_ne`)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** stated and proved fully generically — `xStep` only ever needs $D_1/\text{hD}_1\text{nomin}$, `yStep` only $D_0/\text{hD}_0\text{nomin}$, never the full two-sided `AtomPair` context — and placed *before* section `AtomPair` for exactly that reason: an earlier draft defined them *inside* the section and hit an `Application type mismatch` (Lean’s `include` directive silently

prepended every section variable, e.g. `hD0pos`, onto their signatures even though unused, so a call like `xStep_disjoint_of_ne hD1nomin` bound `hD1nomin` to the wrong parameter slot). `noncomputable`, since both are built from `splitChoice'` (8.12(c)(iii), itself `noncomputable` via `Classical.choice`).

Exercise 8.12(c)(v)(3)

- **Mathematical Target:** the glue connecting `atomPair`'s own recursive `let`-chain to the `xStep/yStep` decomposition: `atomPair_succ_eq (atomPair δ (n+1) = yStep D0 hD0nomin (xStep D1 hD1nomin A B (X n) (δ n).1).1 (xStep ...).2 (Y n) (δ n).2), xStep_spec (the xStep output satisfies exactly the SplitSpec' preconditions yStep needs to fire its own lemmas), and atomPair_congr (sign sequences agreeing below n give an identical depth-n pair)`
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `atomPair_succ_eq` is proved by `rfl` outright — both sides unfold to the identical (A2,B2) pair, since `xStep/yStep` are themselves just `xyStep` unfolded to the same `if-then-else` shape `atomPair`'s own definition already uses; this is what lets later lemmas manipulate the sub-steps algebraically instead of re-deriving the unfolding by hand each time. `xStep_spec` mirrors the corresponding step inside (iv)'s `atomPair_invariant` induction (Boolean-closure for the direct side via `inter_mem_or_empty/diff_mem_or_empty`, `splitChoice'_isSplitSpec` for the split side). `atomPair_congr`'s statement only mentions `D0,D1,hD0nomin,hD1nomin,X,Y` — not the `Positivity/DiffClosed/enumeration-membership/nonem` hypotheses also in scope in section `AtomPair` — so it is declared with `omit hD0pos hD0diff hD1pos hD1diff hXmem hYmem hD0mne hD1mne` in to drop those from its automatically-included section-variable arguments (the `omit ... in` modifier must precede the doc-string, not follow it, else Lean's parser rejects it).

Exercise 8.12(c)(v)(4)

- **Mathematical Target:** monotonicity of `atomPair` on both sides: `atomPair_fst_subset/atomPair_snd_subset`, i.e. `atomPair  $\delta$  (n+1)  $\subseteq$  atomPair  $\delta$  n` componentwise
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** direct consequence of (v)(2)/(v)(3)'s lemmas chained through `atomPair_succ_eq`: the α -side goes through `yStep_fst_subset` (needs (v)(3)'s `xStep_spec` for its `SplitSpec'` preconditions) and then `xStep_fst_subset` (unconditional); the β -side through `yStep_snd_subset` (unconditional) and then `xStep_snd_subset` (needs (iv)'s `atomPair_invariant` for its preconditions at the *previous* depth).

Exercise 8.12(c)(v)(5)

- **Mathematical Target:** the headline theorem `atomPair_disjoint`: for sign sequences δ, δ' disagreeing somewhere below depth `n`, `atomPair  $\delta$  n` and `atomPair  $\delta'$  n` are disjoint on *both* sides at once
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** induction on `n`, mirroring `Theorem88.lean`'s `atomU_invariant` disjointness clause but two-sided throughout. “Disagree below `n`”: recurses via `ih` and shrinks via (v)(4)'s `atomPair_fst_subset/atomPair_snd_subset`. “Agree below `n`, disagree exactly at `n`”: (v)(3)'s `atomPair_congr` first identifies the two depth-`n` ancestors as equal; then splits on *which* sub-step first disagrees — if the `X`-sub-step disagrees, (v)(2)'s `xStep_`

`disjoint_of_ne` gives disjointness of the `xStep` outputs outright, and both `yStep` outputs shrink into their respective already-disjoint `xStep` halves via (v)(2)’s subset lemmas; if the X-sub-step agrees (so the Y-sub-step must disagree), (v)(3)’s `atomPair_succ_eq` unifies both `xStep` applications (since they now have identical inputs), and (v)(2)’s `yStep_disjoint_of_ne` finishes directly, using (v)(3)’s `xStep_spec` for its preconditions. `lake build green, zero sorry; #print axioms on atomPair_disjoint` (and on all of (v)(1)–(v)(4)’s headline lemmas) gives `[propext, Classical.choice, Quot.sound]`, matching the pre-existing baseline for this classical two-sided back-and-forth — the `Classical.choice` is inherited from `splitChoice`’ (8.12(c)(iii)), not new taint.

Exercise 8.12(c)(vi)

- **Mathematical Target:** Part 6 of 7 — bidirectional `Yseq`-analogue closed forms and transfer lemmas: $X \text{ n/Y n}$ are each recoverable as a finite union of matched `atomPair` atoms, with subset/inter-empty/inter-eq transfer in both directions (mirroring `Theorem88.lean`’s `transfer_subset_iff/transfer_inter_eq_iff`, but two-way)
- **Lean File:** — (not yet started; umbrella, see sub-items 8.12(c)(vi)(1)–8.12(c)(vi)(7) below for the planned breakdown)
- **Proof Notes:** the bulk of the remaining size estimate — comparable to the rest of `Theorem88.lean` (`Yseq` onward, ~350 lines: `extendTrue/restrictFin` bookkeeping, `Yseq/splitfst_eq_inter_Yseq/atomU_succ_eq/atomU_eq_genAtom` closed form, `transfer_dir/transfer_empty_iff/transfer_subset_iff/transfer_inter_empty_iff/transfer_double_subset_iff/transfer_inter_eq_iff`, `Yseq_empty_or_mem/Yseq_nonempty_of_mem`), done twice (once per direction) plus interleaving glue. **Pre-planned into 7 sub-sub-parts** (before any code is written, mirroring how (c) itself and (c)(v) were pre-/post-planned) based on close reading of `Theorem88.lean`’s reference structure — see sub-rows for the full breakdown and rationale, **corrected mid-stream at (vi)(4)** (see that row): the originally-planned “bridge to (vi)(1)–(vi)(3)’s abstract `atomE`” turned out to be mathematically false (not just hard), so (vi)(4)-onward instead builds a bespoke two-sided closed-form apparatus directly against `atomPair`’s own invariants — (vi)(1)–(vi)(3) remain `Pass`, valid, reusable general theory, just not plugged into `atomPair` after all. **Key extra difficulty not present in Theorem 8.8’s one-sided case:** `Theorem88.lean`’s `Yseq/transfer` apparatus is generic over an abstract `split` function but *hardcoded to the target U* (`U.master`, `U.mem` appear directly), **and** its D-side atom (`genAtom`) is always a *free* Boolean combination, never itself split — whereas in the two-sided `atomPair` construction, *both* sides are choice-split (each one is the “other side’s” D-side and U-side by turns), so neither reduces to a `genAtom`-driven one-sided recursion; the closed-form/transfer layer must be re-derived directly against `atomPair`’s interleaved `xStep/yStep` structure.

Exercise 8.12(c)(vi)(1)

- **Mathematical Target:** Generalize `Theorem88.lean`’s core `Yseq` closed-form apparatus (`Yseq`, `subset_Yseq`, `splitfst_eq_inter_Yseq`, `atomU_subset_master`, `atomU_succ_eq`, `atomU_eq_genAtom`) from the hardcoded target `U` to an abstract atomless `E` (`SplitSpec`’ `E split`, `E.master`, `E.mem`) — the `Yseq`-analogue of (iii)’s `exists_split → exists_split`’ generalization, but for the closed-form layer built on top
- **Lean File:** `Scott1980/Neighborhood/Exercise812cYseq.lean`
- **Proof Notes:** as anticipated, `extendTrue/restrictFin` and the generic `genAtom` lemmas (`genAtom_subset/genAtom_congr/genAtom_forward/genAtom_self`) were reused **verbatim** from `Theorem88.lean`, no re-proving needed. New: `atomE E split X Δ δ n`

(the `atomU`-analogue, taking `E/``split` as its own explicit leading parameters — **needed** even though both are already section variables in scope, mirroring `atomU`’s own (`split : ...`) re-declaration: a recursive `def` does *not* pick up variables used only in its equations unless they’re part of its own declared signature, unlike `theorem/include`, which force inclusion regardless of use — confirmed by a direct `#check/toy-example` test this session) with `atomE_zero/atomE_succ/atomE_congr`; the core `atomE_invariant` (needs `hΔ : Δ.Nonempty`, `hEmne : E.master.Nonempty` as an extra explicit hypothesis replacing `Theorem88.lean`’s hardcoded `U.master ≠ ∅` witness computation, **and** `hsplit : SplitSpec' E split`); `atomE_succ_subset`; `YseqE/subset_YseqE` (declared `omit hΔ hEmne hsplit in`, mirroring `Yseq/subset_Yseq`’s own `omit`); the “I-formula” `splitfst_eq_inter_YseqE` (verbatim transcription, the hardest single lemma, using the disjointness clause of `atomE_invariant`); `atomE_subset_master`; the closed-form `atomE_succ_eq`; and `atomE_eq_genAtom` (`atomE` coincides with `genAtom (YseqE ...)` `E.master`). Genuinely mechanical once the `atomE/variable` signature quirk above was found — a one-for-one transcription of `Theorem88.lean` lines 223–484 with `U→E`, `Set Q→Set γ`, `atomU→atomE`, `Yseq→YseqE`, `SplitSpec→SplitSpec'`, `splitfst_subset→splitfst_subset'` (already generalized in (iii)). Zero sorry; lake build (3163 jobs) green; `#print axioms on atomE_invariant/atomE_succ_subset/splitfst_eq_inter_YseqE/atomE_subset_master/atomE_succ_eq/atomE_eq_genAtom` all give  $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ , matching the existing baseline (choice inherited from `splitChoice'`, 8.12(c)(iii)).

Exercise 8.12(c)(vi)(2)

- **Mathematical Target:** Generalize the finite-constraint transfer lemma and its corollaries (`transfer_dir`, `transfer_empty_iff`, `transfer_subset_iff`, `transfer_inter_empty_iff`, `transfer_double_subset_iff`, `transfer_inter_eq_iff`) to the same abstract atomless `E` from (vi)(1)
- **Lean File:** `Scott1980/Neighborhood/Exercise812cYseq.lean` (`transfer_dir` itself: `Scott1980/Neighborhood/Theorem88.lean`, un-private’d for reuse)
- **Proof Notes:** confirmed as anticipated — `transfer_dir` needed **zero** re-proof, only its `private` modifier removed (it was already stated fully generically over two independent carrier types $\beta_1 \beta_2$, connected only by a `genAtom`-emptiness correspondence `hcore`; `private` blocks cross-file reuse regardless of genericity). The five corollaries (`transfer_empty_iffE/transfer_subset_iffE/transfer_inter_empty_iffE/transfer_double_subset_iffE/transfer_inter_eq_iffE`) are one-for-one transcriptions of `Theorem88.lean`’s originals with `U.master→E.master/Yseq→YseqE/atomU_invariant→atomE_invariant/atomU_eq_genAtom→atomE_eq_genAtom`, all already available from (vi)(1). **One accounting correction found while implementing:** `transfer_inter_eq_iff`’s proof genuinely needs `Yseq_subset_master` (not just the `transfer_*` family) — planned for (vi)(3) — so a new `YseqE_subset_master` (one-line, via (vi)(1)’s `atomE_subset_master`) was added here instead of deferred, pulled forward from (vi)(3)’s scope (mirrors the project’s precedent of adjusting sub-part boundaries once code is actually written, e.g. (c)(v)’s post-hoc 5-way split). Zero sorry; whole-project lake build (3163 jobs) green; `#print axioms on transfer_dir/transfer_empty_iffE/transfer_subset_iffE/transfer_inter_empty_iffE/transfer_double_subset_iffE/YseqE_subset_master/transfer_inter_eq_iffE` all give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the existing baseline.

Exercise 8.12(c)(vi)(3)

- **Mathematical Target:** Generalize the nonemptiness/membership facts (`Yseq_subset_master`, `Yseq_zero_eq_master`, `Yseq_empty_or_mem`, `Yseq_nonempty_of_mem`) to the abstract atomless `E` from (vi)(1)

- **Lean File:** Scott1980/Neighborhood/Exercise812cYseq.lean (Yseq_subset_master’s analogue YseqE_subset_master was already added in (vi)(2), pulled forward since transfer_inter_eq_iffE needed it directly); new generic union-closure lemmas in Scott1980/Neighborhood/Exercise812cYseq.lean
- **Proof Notes:** completes “(vi)(1)–(vi)(3): the abstract, single-family, one-sided Yseq-apparatus over any atomless E” — the piece that, once done, can be instantiated twice (§(vi)(5)/(vi)(6)) without re-deriving any of this general theory a second time. YseqE_zero_eq_master/YseqE_nonempty_of_mem are one-for-one transcriptions of Yseq_zero_eq_master/Yseq_nonempty_of_mem, with $\text{atom}U \mapsto \text{atom}E / U.\text{master} \mapsto E.\text{master} / U.\text{master_mem} \mapsto E.\text{master_mem}$ ’s destructured nonemptiness (.2.1, specific to U’s concrete mem unfolding) replaced by the already-available hEmne : E.master.Nonempty — genuinely mechanical. YseqE_empty_or_mem was the one real gap, not a transcription: Theorem88.lean’s Yseq_empty_or_mem leans on U_iUnion_mem (Definition87.lean), proved *directly from U’s presented-interval list structure* (presentedIntervals_append), which an abstract E simply does not have. Closed it with genuinely new generic content in Exercise812c.lean: union_eq_master_diff_inter_compl (the De Morgan identity $X \cup Y = M \setminus ((M \setminus X) \cap (M \setminus Y))$ for $X, Y \subseteq M$, pure set algebra via tauto), union_mem_or_empty (any IsPositive+DiffClosed system is automatically closed under binary union of mem-or- $\emptyset$ sets — DiffClosed gives $M \setminus X / M \setminus Y$ mem-or- $\emptyset$, IsPositive gives their intersection mem-or- $\emptyset$, one more DiffClosed application recovers $X \cup Y$), and iUnion_mem_or_empty (Fintype-indexed version, Finset.induction_on fold, identical shape to U_iUnion_mem/V_iUnion_mem’s own folds but with the new generic one-step lemma). Needed two new explicit hypotheses hEpos : E.IsPositive/hEdiff : E.DiffClosed on YseqE_empty_or_mem alone (not threaded into the rest of the file, since no other (vi)(1)–(vi)(3) lemma needs them) — exactly the properties D_0/D_1 already carry in Exercise812c.lean’s section AtomPair (hD0pos/hD0diff/hD1pos/hD1diff), so (vi)(5)/(vi)(6)’s instantiations will have them for free. Zero sorry; whole-project lake build (3163 jobs) green; #print axioms on all six new theorems (union_eq_master_diff_inter_compl/union_mem_or_empty/iUnion_mem_or_empty/YseqE_zero_eq_master/YseqE_empty_or_mem/YseqE_nonempty_of_mem) give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the existing baseline.

Exercise 8.12(c)(vi)(4)

- **Mathematical Target:** ~~Identify atomPair’s per-side trajectory with an instance of (vi)(1)–(vi)(3)’s single-family atomE~~ (**corrected**): recover $X \cap Y$ as unions of atomPair-derived “half-step” pieces on the *other* side, built directly against atomPair’s own already-proven invariants — umbrella, see sub-items (vi)(4)(a)–(vi)(4)(d) below
- **Lean File:** Scott1980/Neighborhood/Exercise812c.lean
- **Proof Notes:** the original pre-plan’s literal “bridge to atomE” is false, not just difficult — discovered by direct calculation, not just difficulty in formalizing. atomE’s testing family $\text{genAtom } X \Delta \delta \ n$ is a *free* Boolean combination, only ever intersected/subtracted directly, never itself split; but atomPair’s A-component *is* itself choice-split at every Y-sub-step (via $D_0.\text{NoMinimal}$, exists_split’s genuine-split case), so whenever that case fires (generically), the real A_n is a **proper subset** of $\text{genAtom } X$. $D_0.\text{master } \delta_1 \ n$ ($\delta_1 \ k := (\delta \ k).1$) — concretely, A_1 is the NoMinimal-produced piece $I2/J2$, strictly smaller than $A1_0 = \text{genAtom}(\dots)$ whenever $B1_0$ splits nontrivially. So *both* atomPair components are “atomE-like” (choice-driven); *neither* is “genAtom-like” (free), unlike Theorem88.lean’s one-sided case where D’s side stayed free by construction. Exercise812cYseq.lean’s (vi)(1)–(vi)(3) apparatus is therefore not reused here — it remains valid, correct, reusable general theory for any genuinely *one-sided* abstract E, just not what this specific two-sided bridge needs. **The actual fix:** re-derive Yseq’s

“I-formula” argument *directly* against `atomPair`, reusing only already-Pass lemmas from (iv)/(v) — no `atomE` involved. Broken into 4 sub-sub-sub-parts (post-hoc, once the correction above was found) mirroring the natural def/bridge/I-formula split of the work: (a) the X n -side closed form (simpler — no `Function.update` needed); (b)–(d) the Y n -side closed form (harder — genuinely needs a `Function.update`-style bit-realization bridge, (c), matching `Theorem88.lean`’s own `splitfst_eq_inter_Yseq` after all).

Exercise 8.12(c)(vi)(4)(a)

- **Mathematical Target:** The X n -side half-step closed form: recover X n as a union of `atomPair`’s D_1 -side half-step pieces (the X -sub-step’s “+” branch, *before* the following Y -sub-step refines it further)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** new generic two-sided sign-sequence padding `extendTruePair/restrictFinPair` (componentwise `extendTrue/restrictFin`, `Theorem88.lean`) with `extendTruePair_restrictFinPair_agree`, plus `XPseq n : Set  $\beta$` (union over depth- n histories of the D_1 -piece chosen by the X -sub-step’s “+” branch, via `xStep` directly with argument `true`) with `subset_XPseq` and the headline `xStep_snd_eq_inter_XPseq` (the I-formula: X n ’s “+” branch on any history δ is exactly $(\text{atomPair } \delta \ n).2 \cap \text{XPseq } n$), proved via `atomPair_invariant/atomPair_congr/atomPair_disjoint` ((iv)/(v)) and `xStep_snd_subset` ((v)(2)). **Simpler than Y seq’s own proof** in one respect: since the branch is a literal `true` argument (not δ n ’s own value), no `Function.update`-based “ $\delta 2$ ” detour is needed — agreement below n alone suffices, because `atomPair  $\delta$  n` only ever depends on δ strictly below n . Zero sorry; lake build (3163 jobs) green; #print axioms on `extendTruePair_restrictFinPair_agree/subset_XPseq/xStep_snd_eq_inter_XPseq` give $\subseteq \{\text{proptext}, \text{Classical.choice}, \text{Quot.sound}\}$ (the first is actually choice-free, $\subseteq \{\text{proptext}\}$), matching/improving on the existing baseline.

Exercise 8.12(c)(vi)(4)(b)

- **Mathematical Target:** Define the Y n -side half-step closed form `YPseq n : Set  $\alpha$` , together with its trivial monotonicity fact
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** unlike X n ’s side, `yStep`’s own inputs (`A1`, `B1`, the *post- X* -sub-step values) already depend on $(\delta \ n).1$ itself, not just history strictly below n — so `YPseq`’s union needs an *extra* free `Bool` parameter `bx` (for position n ’s X -sub-step bit) alongside the usual `Fin n  $\rightarrow$  Bool  $\times$  Bool` history: `YPseq n :=  $\bigcup$  ( $\delta'$  : Fin n  $\rightarrow$  Bool  $\times$  Bool) (bx : Bool), (yStep  $D_0$  hD0nomin  $A1$   $B1$  ( $Y$   $n$ ) true).1` where $A1/B1$ are `xStep`’s outputs at bit `bx` applied to `atomPair (extendTruePair  $\delta'$ ) n`. `subset_YPseq` is the resulting (doubly-indexed) `Set.subset_iUnion` fact — literally `Set.mem_iUnion.mpr` twice, exactly as trivial as `subset_XPseq`.

Exercise 8.12(c)(vi)(4)(c)

- **Mathematical Target:** A reusable bridging lemma (`xStep_spec_bit`): the `SplitSpec'` preconditions `yStep` needs, transported across the X -sub-step, at an *arbitrary* bit `bx` (not just δ n ’s own first component) — connecting an arbitrary (δ', bx) witness of `YPseq n` back to a concrete history
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`

- **Proof Notes:** mirrors Theorem88.lean’s `Function.update`-based δ_2/δ_3 device inside `split_fst_eq_inter_Yseq` (needed there because `atomU`’s recursion threads δ ’s own value into its depth- $n+1$ step): set $\delta'' := \text{Function.update } (\text{extendTruePair } (\text{restrictFinPair } \delta \ n)) \ n \ (\text{bx}, \text{true})$ (second component of the update irrelevant/arbitrary, unused elsewhere) — agrees with δ strictly below n (`Function.update_of_ne + extendTruePair_restrictFinPair_agree`) with $(\delta'' \ n).1 = \text{bx}$ exactly (`Function.update` at the point of update, closed by `simp`) — then `xStep_spec` at δ'' , transported by `atomPair_congr`’s agreement fact and the bit fact, gives `xStep_spec_bit` directly (`rwa [hcongr, hbit]` at `hspec`). A genuinely reusable drop-in generalization of `xStep_spec` (which is the `bx := (\delta \ n).1` special case).

Exercise 8.12(c)(vi)(4)(d)

- **Mathematical Target:** The Y n -side “I-formula” `yStep_fst_eq_inter_YPseq`: for any history δ and depth n , the Y -sub-step’s “+” branch (applied to the post- X -sub-step values at δ ’s own bit $(\delta \ n).1$) equals $(\text{xStep-fst-output-at-}(\delta \ n).1) \cap \text{YPseq } n$
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** assembles (vi)(4)(b)+(vi)(4)(c) with `xStep_spec_bit/yStep_fst_subset/xStep_disjoint_of_ne/xStep_fst_subset/atomPair_disjoint/atomPair_invariant` (all already `Pass`), by the same two-sided antisymmetry argument as `xStep_snd_eq_inter_XPseq`, but the $\supseteq$ direction now needs a genuine 3-way case split on the union witness (δ', bx) (`XPseq`’s proof only needed 2): (i) history agrees below n and $\text{bx} = (\delta \ n).1$ — literally the same J after two rewrites; (ii) history agrees below n but $\text{bx} \neq (\delta \ n).1$ — `xStep_disjoint_of_ne` (at δ ’s own A, B) plus `xStep_spec_bit-at-bx` gives disjoint `xStep-.1` outputs; (iii) history disagrees strictly below n — `atomPair_disjoint`’s $.1$ clause, with `xStep_fst_subset` (unconditional) bounding both the witness’s and δ ’s own `xStep-.1` output back up to the full `atomPair-.1` values before applying disjointness (needed one extra step here vs. `XPseq`’s proof, since `hzA1 : z ∈ A1` isn’t literally `z ∈ (atomPair  $\delta \ n$ ).1`). Zero sorry; whole-project lake build (3163 jobs) green; `#print axioms on subset_YPseq/xStep_spec_bit/yStep_fst_eq_inter_YPseq` all give $\subseteq \{\text{propxt}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the baseline.

Exercise 8.12(c)(vi)(5)

- **Mathematical Target:** ~~applying (vi)(1)–(vi)(4) with $E := D_0$ to conclude $Y \ n$ is recoverable as a union of matched α -side atoms, with `subset/inter-empty/inter-eq` transfer facts (corrected):~~ this pre-plan is superseded by (vi)(4)’s own correction (there is no $E := D_0$ instantiation to apply). **First, achievable piece (done):** `XPseq n/YPseq n` are always D_1/D_0 -mem-or- $\emptyset$ and $\subseteq$ the relevant master. **Remaining piece, now scoped into 4 sub-sub-sub-parts (a)–(d) below:** the order/intersection transfer layer itself ($X \ i \subseteq X \ j \leftrightarrow \text{XPseq } i \subseteq \text{XPseq } j$, and symmetrically for Y/YPseq , plus `inter-empty/inter-eq` analogues), via a genuinely new **joint two-family atom system**
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean` (`mem-or- $\emptyset$ /subset-of-master` facts, done); umbrella for the remaining transfer layer — see sub-items 8.12(c)(vi)(5)(a)–8.12(c)(vi)(5)(d) below for the scoped breakdown
- **Proof Notes:** the full pre-planned content — an order/intersection “transfer” layer recovering facts like $X \ i \subseteq X \ j \leftrightarrow \text{XPseq } i \subseteq \text{XPseq } j$ (mirroring Theorem88a.lean’s `embed_subset_iff`, needed for the eventual `DomainIso` assembly) — turns out to need a genuinely **new joint two-family atom/genAtom-style apparatus** (testing points against *several* X/Y indices at once), not just the single-index `XPseq/YPseq` built in (vi)(4):

unlike `Theorem88a.lean`’s `idxSet` (always non-empty by pure index bookkeeping, independent of `D`’s own `mem` structure), `atomPair`’s atoms can genuinely vanish, so relating *two* indices’ inclusion needs evaluating a *joint* atom — exactly why `Theorem88.lean`’s own `genAtom/transfer_empty_iff` apparatus takes finite *lists* of constraints rather than single indices.

Scoping pass (2026-07-04), before any further code: re-examined `atomPair`’s own recursive step (`atomPair_succ_eq = yStep ∘ xStep`) at the level of individual *half*-steps rather than full steps. Key observation: the `X`-sub-step’s direct α -output ($A \cap X_n / A \setminus X_n$) is *already* a literal `genAtom`-style formula against the family `X`, and (by (vi)(4)(d)’s `yStep_fst_eq_inter_YPseq`) the `Y`-sub-step’s choice-driven α -output is, on its “+” branch, *also* a literal `genAtom`-style formula against the family `YPseq` — so `(atomPair  $\delta$  n).1`, unrolled one half-step at a time, is *exactly* `genAtom` over the **interleaved** family `combinedX` : $\mathbb{N} \rightarrow \text{Set } \alpha$ with `combinedX (2k) := X k`, `combinedX (2k+1) := YPseq k`, tested against the interleaved sign sequence `combined $\delta$   $\delta$` : $\mathbb{N} \rightarrow \text{Bool}$ (`combined $\delta$   $\delta$  (2k) := ( $\delta$  k).1`, `combined $\delta$   $\delta$  (2k+1) := ( $\delta$  k).2`). Symmetrically, `(atomPair  $\delta$  n).2` is `genAtom` over `combinedY` (`combinedY (2k) := XPseq k`, `combinedY (2k+1) := Y k`, against the *same* `combined $\delta$   $\delta$`). Once both sides are literal `genAtoms` over a shared sign sequence, `Theorem88.lean`’s fully generic `transfer_dir/transfer_empty_iff/transfer_subset_iff/transfer_inter_empty_iff/transfer_double_subset_iff/transfer_inter_eq_iff` become directly reusable (none are `private`, confirmed) exactly as (vi)(2) reused `transfer_dir` — specializing the reused lemmas to even/even or odd/odd index pairs (`2i, 2j` or `2i+1, 2j+1`) unwinds `combinedX/combinedY` back to literal `X i  $\subseteq$  X j / XPseq i  $\subseteq$  XPseq j`-style statements. This is a materially smaller plan than the initial “substantial, unscoped new work” estimate, because it needs **no** new disjointness or invariant proof: the two ingredients `transfer_dir` needs (matching-emptiness `hcore`, and — internally, already consumed by (vi)(4) — pairwise disjointness) are *already available* half-step-by-half-step as `atomPair_invariant` (full-step/even case) and `xStep_spec_bit` (half-step/odd case, already proved in (vi)(4)(c)). The only genuinely new content is (a) below (completing (vi)(4)’s one-branch I-formulas into full closed forms) and the bookkeeping of (b)–(d). Broken into 4 sub-sub-sub-parts, mirroring (vi)(4)’s own post-hoc (a)–(d) split:

- (a) the “else-branch” closed-form algebra completing (vi)(4)(a)/(d)’s one-branch (`true`-only) I-formulas into full two-branch closed forms (mirroring `Theorem88.lean`’s `atomU_succ_eq`, which derives its `false` branch from its `true` branch plus `SplitSpec`’s `I  $\cup$  J = B / I  $\cap$  J =  $\emptyset$`) — needed so `xStep`’s/`yStep`’s outputs match `genAtom`’s own `if  $\delta$  then Z else M  $\setminus$  Z` recursive shape at *both* signs, not just `true`.
- (b) the interleaved families `combinedX/combinedY` and shared sign-interleaving map `combined $\delta$` , plus the closed-form identification theorems (`(atomPair  $\delta$  n).1 = genAtom combinedX D0.master (combined $\delta$   $\delta$ ) (2*n)`, and the odd-depth half-step analogue; symmetrically for `combinedY/.2`) — proved by a single two-half-steps-at-a-time induction using (a).
- (c) assembling the `hcore` fact $\forall \delta' n, \text{genAtom combinedX } D_0.\text{master } \delta' n = \emptyset \leftrightarrow \text{genAtom combinedY } D_1.\text{master } \delta' n = \emptyset$ for an *arbitrary* $\delta' : \mathbb{N} \rightarrow \text{Bool}$ (via de-interleaving δ' into a $\mathbb{N} \rightarrow \text{Bool} \times \text{Bool}$ history and re-applying (b)) from `atomPair_invariant` (even depths) and `xStep_spec_bit` (odd depths) — pure assembly, no new mathematical content.
- (d) instantiating `Theorem88.lean`’s `transfer_dir/transfer_empty_iff/transfer_subset_iff/transfer_inter_empty_iff/transfer_double_subset_iff/transfer_inter_eq_iff` with `Z1 := combinedX`, `M1 := D0.master`, `Z2 := combinedY`, `M2 := D1.master`, `hcore` from (c) (verbatim reuse, mirroring (vi)(2)’s precedent), then specializing to even/even and odd/odd index pairs to extract and state the headline

bidirectional facts: $X \text{ i} \subseteq X \text{ j} \leftrightarrow \text{XPseq i} \subseteq \text{XPseq j}$, $Y \text{ i} \subseteq Y \text{ j} \leftrightarrow \text{YPseq i} \subseteq \text{YPseq j}$, and their inter-empty/inter-eq analogues — the actual deliverable this sub-part exists for.

Already Pass (unaffected by the above scoping, kept in this row for continuity): reusing (vi)(3)’s fully generic `iUnion_mem_or_empty` (no new theory needed): `atomPair_fst_subset_master/atomPair_snd_subset_master` (`atomPair`’s sides are always $\subseteq D_0.\text{master}/D_1.\text{master}$, by induction from the base case and `atomPair_fst_subset/atomPair_snd_subset`, (v)(3)); then `XPseq_subset_master/XPseq_empty_or_mem` (via `xStep_snd_subset+atomPair_invariant`, and `iUnion_mem_or_empty` fed each `xStep` “+”-branch’s own `SplitSpec`’ `mem-or- $\emptyset$` guarantee) and the symmetric `YPseq_subset_master/YPseq_empty_or_mem` (via `yStep_fst_subset/xStep_fst_subset+xStep_spec_bit`, `iUnion_mem_or_empty` applied twice for `YPseq`’s doubly-indexed union). Zero sorry; whole-project lake build (3163 jobs) green; `#print axioms` on all six theorems give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the baseline.

Exercise 8.12(c)(vi)(5)(a)

- **Mathematical Target:** Complete (vi)(4)(a)/(d)’s one-branch (`true-only`) I-formulas (`xStep_snd_eq_inter_XPseq`, `yStep_fst_eq_inter_YPseq`) into full two-branch closed forms giving `xStep`’s/`yStep`’s output at *either* sign directly in terms of `XPseq n/YPseq n` — the two-sided, half-step analogue of `Theorem88.lean`’s `atomU_succ_eq`
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `xStep_snd_succ_eq`: (`xStep D1 hD1nomin (atomPair δ n).1 (atomPair δ n).2 (X n) b).2 = (atomPair δ n).2 $\cap$ (if b then XPseq n else D1.master \ XPseq n), and yStep_fst_succ_eq: the symmetric YPseq/ α -side statement, at an arbitrary bit b for the Y-sub-step itself but with the X-sub-step’s own bit kept fixed at (δ n).1 (exactly as yStep_fst_eq_inter_YPseq already does) — confirmed during implementation that no further xStep_spec_bit-style generalization of the X-bit is needed, since (b)’s planned combined-family recursion only ever calls this at δ ’s own bit. Both proofs follow atomU_succ_eq’s exact recipe: the true branch is the already-proved I-formula (xStep_snd_eq_inter_XPseq/yStep_fst_eq_inter_YPseq); the false branch is derived algebraically from it plus SplitSpec’s $I \cup J = B/I \cap J = \emptyset$ (via splitChoice'_isSplitSpec, instantiated at the matching-emptiness/mem-or- $\emptyset$ facts from atomPair_invariant/xStep_spec respectively) — genuinely mechanical, no new disjointness or invariant content, matching the plan exactly. One small bookkeeping move made during implementation: atomPair_fst_subset_master/atomPair_snd_subset_master (originally proved later, alongside XPseq_subset_master etc.) were relocated earlier in the file (right after atomPair_snd_subset), since both only depend on atomPair_fst_subset/atomPair_snd_subset (v)(3) and are needed here (to convert B \ XPseq n into B $\cap$ (D1.master \ XPseq n), resp. for YPseq) — pure reordering, no change to their statements or proofs. Zero sorry; whole-project lake build (3163 jobs) green; #print axioms on xStep_snd_succ_eq/yStep_fst_succ_eq/atomPair_fst_subset_master/atomPair_snd_subset_master all give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the baseline.`

Exercise 8.12(c)(vi)(5)(b)

- **Mathematical Target:** Define the interleaved families `combinedX : $\mathbb{N} \rightarrow \text{Set } \alpha$ (combinedX (2k) := X k, combinedX (2k+1) := YPseq k), combinedY : $\mathbb{N} \rightarrow \text{Set } \beta$ (combinedY (2k) := XPseq k, combinedY (2k+1) := Y k), and the shared sign-interleaving map combined δ (δ : $\mathbb{N} \rightarrow \text{Bool} \times \text{Bool}$) : $\mathbb{N} \rightarrow \text{Bool}$ (combined δ δ (2k) := (δ k).1, combined δ`

$\delta (2k+1) := (\delta k).2$); prove `atomPair`’s own values coincide with `genAtom` over these interleaved families at the matching depth (`(atomPair  $\delta$  n).1 = genAtom combinedX D0.master (combined $\delta$   $\delta$ ) (2 * n)`), plus the odd-depth half-step statement identifying `genAtom combinedX D0.master (combined $\delta$   $\delta$ ) (2 * n + 1)` with the X-sub-step’s own direct α -output; symmetrically for `combinedY/.2`) — the two-sided analogue of Theorem88.lean’s `atomU_eq_genAtom`

- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `combinedX/combinedY/combined $\delta$` defined exactly as planned; per-parity unfolding lemmas `combinedX_even/combinedX_odd/combinedY_even/combinedY_odd/combined $\delta$ _even/combined $\delta$ _odd` (`rw [if_pos/if_neg (by omega), show (2*k)/2 = k from by omega]`). The two headline theorems (`atomPair_fst_eq_genAtom/atomPair_snd_eq_genAtom`) are each a single induction `n` whose `succ` case chains: `atomPair_succ_eq` (unfold to `yStep  $\circ$  xStep`) $\rightarrow$ (a)’s `yStep_fst_succ_eq/xStep_snd_succ_eq` closed form at the *other* sub-step’s own bit $\rightarrow$ `genAtom_succ'` (a `rfl`-restated rewritable form of `genAtom`’s equation, added since `genAtom` itself is a raw pattern-match `def`) $\rightarrow$ the odd-depth half-step lemma (`genAtom_combinedX_succ_eq/genAtom_combinedY_succ_eq`, proved separately, themselves one `genAtom_succ'` + parity-unfold + (a)’s *other* closed form) — the two chains meet and close by `rfl` (automatic after the final `rw`). Matches the planned “two half-steps per level” structure exactly, `atomPair_fst_eq_genAtom`’s step performing the elementary X-half then (a)’s `yStep_fst_succ_eq`, and symmetrically.

Debugging note (real, not hypothetical) — a second instance of the (vi)(5)(a)-documented include/omit pitfall, one level subtler: `combined $\delta$ _even/combined $\delta$ _odd`’s own `omit hD0pos hD0diff hD1pos hD1diff hXmem hYmem hD0mne hD1mne` in an annotation (copied from the neighboring `combinedX_even/combinedY_even`, which *do* need `D0 D1 hD0nomin hD1nomin`) omitted only 8 of the section’s 10 blanket-included hypotheses, leaving `hD0nomin/hD1nomin` (and transitively `D0/D1`, since `hD0nomin : D0.NoMinimal` depends on `D0`) force-included as *unused* leading parameters — even though `combined $\delta$ _even`’s statement (`combined $\delta$   $\delta$  (2*k) = ( $\delta$  k).1`) never mentions any of `D0/D1/hD0nomin/hD1nomin`. Bare `rw [combined $\delta$ _even]` cannot unify these phantom parameters from the rewrite pattern (they don’t occur in it), leaving them as dangling metavariables that Lean reports as bizarre leftover goals (`⊢ NeighborhoodSystem ?m, ⊢ NoMinimal ?D0, ⊢ Type ?u`) attached to the *enclosing* theorem’s `:=` by position — easily mistaken for an elaborator bug in the surrounding proof, especially since the goals cascade to every caller (`genAtom_combinedX_succ_eq/Y`, then `atomPair_fst/snd_eq_genAtom`) and persist even with the caller’s body replaced by `sorry` (since the phantom metavariables are created by elaborating the `rw` lemma itself, before the tactic block even runs). Root-caused by explicitly supplying `combined $\delta$ _even`’s “hidden” args (`combined $\delta$ _even D0 D1 hD0nomin hD1nomin  $\delta$  n`) and observing the resulting *genuine* type mismatch (`$\delta$` provided where `D0 : NeighborhoodSystem ?m` was expected) — confirming the extra params existed and were simply never constrained. **Fix:** extend both `omit` lines to the *full* 10-name list (adding `hD0nomin hD1nomin`), matching `combined $\delta$` ’s own definition (which has no such annotation at all and correctly stays a bare 2-argument function, since a `def`’s equation-compiler body, unlike a `theorem`’s `included` context, only picks up `variables` actually referenced). **Lesson for future omit lines in this file:** the omitted list must be checked against the *lemma’s actual conclusion*, not copy-pasted from a neighboring lemma that happens to need a different subset of the section’s variables. Zero `sorry`; whole-project lake build green; `#print axioms on atomPair_fst_eq_genAtom/atomPair_snd_eq_genAtom` gives $\subseteq \{\text{propext, Classical.choice, Quot.sound}\}$, matching the baseline (choice inherited from `splitChoice'`, 8.12(c)(iii); no new taint).

Exercise 8.12(c)(vi)(5)(c)

- **Mathematical Target:** The matching-emptiness fact $\forall (\delta' : \mathbb{N} \rightarrow \text{Bool}) \ n, \text{ genAtom combinedX } D_0.\text{master } \delta' \ n = \emptyset \leftrightarrow \text{ genAtom combinedY } D_1.\text{master } \delta' \ n = \emptyset$ — the `hcore` hypothesis `Theorem88.lean`’s `transfer_dir` needs, for the interleaved families
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean` — umbrella; broken into 4 sub-parts (1)–(4) below, since the single planned paragraph is actually a definition + round-trip lemma + two independent case proofs + a final assembly, not one atomic step
- **Proof Notes:** pure assembly overall, no new mathematical content, but genuinely multiple Lean steps: (1) define the de-interleaving map and prove the round-trip identity feeding both later cases; (2) the even-index case, via (b) + `atomPair_invariant`; (3) the odd-index case, via (b) + `xStep_spec_bit`; (4) assemble (1)–(3) (parity case-split on n) into the headline $\forall \delta' \ n, \dots$ statement. See sub-rows for the scoped breakdown.

Exercise 8.12(c)(vi)(5)(c)(1)

- **Mathematical Target:** Given arbitrary $\delta' : \mathbb{N} \rightarrow \text{Bool}$, de-interleave it into $\delta \ k := (\delta' (2*k), \delta' (2*k+1)) : \mathbb{N} \rightarrow \text{Bool} \times \text{Bool}$, and prove that re-interleaving recovers δ' exactly: `combined $\delta$   $\delta$  =  $\delta'$`
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `deinterleaved $\delta$  ( $\delta' : \mathbb{N} \rightarrow \text{Bool}$ ) (k :  $\mathbb{N}$ ) :  $\text{Bool} \times \text{Bool} := (\delta' (2 * k), \delta' (2 * k + 1))$` (plain def, no section variables needed, mirroring `combined $\delta$` itself). `combined $\delta$ _deinterleaved $\delta$  : combined $\delta$  (deinterleaved $\delta$   $\delta'$ ) =  $\delta'$` : `funext m, unfold combined $\delta$  deinterleaved $\delta$ , split` on the resulting `if`, each branch closed by `rw [show 2 * (m / 2) = m from by omega]` (resp. `+ 1`) — the `Prod.fst/Prod.snd` projections of the literal pair reduce definitionally, so `rw`’s automatic closing `rfl` finishes each branch with no further tactics. Needed the same `omit hD0pos hD0diff hD0nomin hD1pos hD1diff hD1nomin hXmem hYmem hD0mne hD1mne` in annotation as the neighboring `combined $\delta$ _even/combined $\delta$ _odd` (the theorem statement mentions no section variables, but per (b)’s documented `include/omit` pitfall, all ten still needed to be listed to avoid phantom leading parameters). Zero sorry; whole-project `lake build` (3163 jobs) green; `#print axioms on combined $\delta$ _deinterleaved $\delta$` gives $\subseteq \{\text{propext, Quot.sound}\}$ — fully choice-free (no `Classical.choice`), strictly better than the section’s `splitChoice`-tainted baseline, since this lemma is pure arithmetic bookkeeping independent of the atom construction.

Exercise 8.12(c)(vi)(5)(c)(2)

- **Mathematical Target:** The even-index case of `hcore`: `genAtom combinedX D0.master  $\delta'$  (2*n) =  $\emptyset \leftrightarrow \text{ genAtom combinedY } D_1.\text{master } \delta' (2*n) = \emptyset$`
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `hcore_even ($\delta' : \mathbb{N} \rightarrow \text{Bool}$) (n : $\mathbb{N}$): rw [$\leftarrow$ combined δ _deinterleaved δ δ' , $\leftarrow$ atomPair_fst_eq_genAtom ... (deinterleaved δ δ') n, $\leftarrow$ atomPair_snd_eq_genAtom ... (deinterleaved δ δ') n]` reduces the goal to `(atomPair (deinterleaved δ δ') n).1 = $\emptyset \leftrightarrow$ (atomPair (deinterleaved δ δ') n).2 = $\emptyset$` , closed directly by `atomPair_invariant`’s clause `.1` (already `Pass`, (iv)) — exactly the planned direct instantiation, no new content. **One implementation wrinkle:** the naive one-line `rw [$\leftarrow$ atomPair_fst_eq_genAtom, $\leftarrow$ atomPair_snd_eq_genAtom]` (letting Lean infer the lemmas’ leading `D0 D1 hD0pos ... hD1mne` arguments from unification) fails — those hypotheses don’t

occur in the lemmas' conclusion patterns being matched, so `rw` leaves them as unresolved metavariable side-goals ($\vdash D_0.\text{IsPositive}$, $\vdash D_0.\text{master.Nonempty}$, etc., all provable by `assumption` but not auto-discharged by `rw` itself) rather than instantiating them from context; fixed by supplying every leading argument explicitly in the `rw`, mirroring the file's existing calling convention throughout (e.g. `genAtom_combinedX_succ_eq D_0 D_1 hD_0pos hD_0diff hD_0nomin hD_1pos hD_1diff hD_1nomin X Y hXmem hYmem hD_0mne hD_1mne  $\delta$  n hIH`). Zero sorry; whole-project lake build (3163 jobs) green; `#print axioms on hcore_even` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the section's baseline (choice inherited from `atomPair_invariant/splitChoice'`).

Exercise 8.12(c)(vi)(5)(c)(3)

- **Mathematical Target:** The odd-index case of `hcore`: `genAtom combinedX D_0.master  $\delta'$  (2*n+1) =  $\emptyset \leftrightarrow$  genAtom combinedY D_1.master  $\delta'$  (2*n+1) =  $\emptyset$`
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `hcore_odd ($\delta' : \mathbb{N} \rightarrow \text{Bool}$) (n : $\mathbb{N}$): rw [← combined δ _deinterleaved δ' , genAtom_combinedX_succ_eq ... (deinterleaved δ') n (atomPair_fst_eq_genAtom ... (deinterleaved δ') n), genAtom_combinedY_succ_eq ... (deinterleaved δ') n (atomPair_snd_eq_genAtom ... (deinterleaved δ') n)] reduces the goal to (xStep D_1 hD_1nomin A B (X n) bx).1 = $\emptyset \leftrightarrow$ (xStep D_1 hD_1nomin A B (X n) bx).2 = $\emptyset$ (A, B := atomPair (deinterleaved δ') n, bx := (deinterleaved δ' n).1), closed directly by (xStep_spec_bit ... (deinterleaved δ') n bx).1.symm (already Pass, (vi)(4)(c); .symm since xStep_spec_bit's clause is stated .2 = $\emptyset \leftrightarrow$.1 = $\emptyset$, the reverse orientation) — the planned direct instantiation, no new content, and unlike (2) it built clean on the first try (correctly supplying every leading argument to the four rewrite lemmas from the outset, per (2)'s documented lesson). Zero sorry; whole-project lake build (3163 jobs) green; #print axioms on hcore_odd gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the section's baseline.`

Exercise 8.12(c)(vi)(5)(c)(4)

- **Mathematical Target:** Final assembly: $\forall (\delta' : \mathbb{N} \rightarrow \text{Bool}) n, \text{genAtom combinedX } D_0.\text{master } \delta' n = \emptyset \leftrightarrow \text{genAtom combinedY } D_1.\text{master } \delta' n = \emptyset$, the actual `hcore` deliverable of (c)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `hcore ($\delta' : \mathbb{N} \rightarrow \text{Bool}$) (n : $\mathbb{N}$): rcases (by omega : n % 2 = 0 $\vee$ n % 2 = 1) with hn | hn, each branch rw [show n = 2 * (n/2) from by omega] (resp. + 1) then exact hcore_even ... δ' (n/2) / exact hcore_odd ... δ' (n/2) — pure glue, no new content, exactly as planned. Used a hand-rolled omega-derived parity disjunction rather than Nat.even_or_odd/Nat.even_or_odd', matching this file's established style (combined δ _deinterleaved δ , (c)(1)) and the project-wide lesson (HANDOFF, 2026-06-xx Example 6.1 work) that Nat.even_or_odd pulls Classical.choice in the pinned Mathlib — moot for this particular theorem's own axiom footprint (already Classical.choice-tainted via hcore_even/hcore_odd), but kept consistent regardless. Built clean on the first try. Zero sorry; whole-project lake build (3163 jobs) green; #print axioms on hcore gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the section's baseline. This completes Exercise 8.12(c)(vi)(5)(c) — all of (1)–(4) Pass.`

Exercise 8.12(c)(vi)(5)(d)

- **Mathematical Target:** The headline bidirectional transfer facts: $X \ i \subseteq X \ j \leftrightarrow XPseq \ i \subseteq XPseq \ j$, $Y \ i \subseteq Y \ j \leftrightarrow YPseq \ i \subseteq YPseq \ j$, and their inter-empty/inter-eq analogues (mirroring Theorem88.lean's `transfer_subset_iff/transfer_inter_empty_iff/transfer_inter_eq_iff`, doubled for both directions) — the actual deliverable of 8.12(c)(vi)(5), needed for the eventual `DomainIso` assembly in (vii)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes: one correction to the pre-plan:** Theorem88.lean's `transfer_subset_iff/transfer_inter_empty_iff/transfer_double_subset_iff/transfer_inter_eq_iff` (unlike `transfer_dir`, which *is* fully generic and reused verbatim) are hardcoded to the concrete `X/Δ/Yseq split X Δ/U.master`, so — exactly as (vi)(2)'s `Exercise812cYseq.lean` had to build `transfer_*_iffE` transcriptions for the abstract `E` rather than reuse the originals — this needed fresh one-for-one transcriptions for the `combinedX/combinedY` pair: `transfer_empty_combined/transfer_subset_combined/transfer_inter_empty_combined/transfer_double_subset_combined/transfer_inter_eq_combined` ($\Delta \mapsto D_0.master, X \mapsto combinedX, U.master \mapsto D_1.master, Yseq \text{ split } X \Delta \mapsto combinedY$, `transfer_dir`'s `hcore` argument $\mapsto$ (c)'s `hcore`), each a routine transcription (`ext/tauto/Set.diff_eq_empty` bookkeeping identical to the originals). Two new small helper lemmas were needed first, not in the original plan: `combinedX_subset_master/combinedY_subset_master` (`combinedX i/combinedY i` are always $\subseteq D_0.master/D_1.master$ for *arbitrary* `i`, not just even/odd-specialized — via a parity case split unfolding to `D_0.sub_master (hXmem _)/YPseq_subset_master` resp. `XPseq_subset_master/D_1.sub_master (hYmem _)` — needed as `transfer_inter_eq_combined`'s `hi/hk` hypotheses, mirroring Theorem88.lean's own $X \ i \subseteq \Delta$ preconditions on `transfer_inter_eq_iff`). Then the six headline specializations: `X_subset_iff_XPseq_subset/YPseq_subset_iff_Y_subset/X_inter_empty_iff_XPseq_inter_empty/YPseq_inter_empty_iff_Y_inter_empty/X_inter_eq_iff_XPseq_inter_eq/YPseq_inter_eq_iff_Y_inter_eq` — each instantiates the matching `transfer_*_combined` lemma at $(2i, 2j[, 2k])$ (even case) or $(2i+1, 2j+1[, 2k+1])$ (odd case), unfolds via `combinedX_even/combinedX_odd/combinedY_even/combinedY_odd` ((b)), and discharges the resulting $\cap$ `master` bookkeeping via `Set.inter_eq_self_of_subset_right` fed by `D_0.sub_master/D_1.sub_master/XPseq_subset_master/YPseq_subset_master` — exactly the planned `rfl/simp`-level unwinding, no new mathematical content beyond the transcription itself. Zero sorry; whole-project lake build (3163 jobs) green; `#print axioms` on all six headline theorems give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the section's baseline. **This completes Exercise 8.12(c)(vi)(5) — all of (a)–(d) Pass.**

Exercise 8.12(c)(vi)(6)

- **Mathematical Target:** ~~literal mirror of (vi)(5) with the two sides' roles swapped (superseded):~~ folded into (vi)(5) above once it became clear `XPseq/YPseq` (not a fresh $E := D_1$ instantiation) are the right pair of objects, and both sides' `mem-or-∅/subset-of-master` facts were proved together in one pass
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** kept as a placeholder row (rather than deleted) for traceability with earlier `HANDOFF.md` checkpoints that still referred to a separate (vi)(6); see (vi)(5)'s row for the actual content and status. **Reconfirmed (2026-07-04)**, now that (vi)(5) is fully **Pass** end-to-end (sub-parts (a)–(d), with (c) itself complete across (1)–(4)): no work remains under this row — `YPseq_subset_iff_Y_subset/YPseq_inter_empty_iff_Y_inter_empty/YPseq_inter_eq_iff_Y_inter_eq` (the odd-index specializations proved in

(5)(d)) are exactly the “D₁-side”/“swapped-roles” headline facts this row’s original mathematical target was asking for, so there genuinely is nothing left to prove here beyond what (5) already delivered.

Exercise 8.12(c)(vi)(7)

- **Mathematical Target:** Bidirectional glue: whatever additional bridging (vii)’s final assembly needs to combine (vi)(5)’s and (vi)(6)’s two one-sided closed forms into a single, mutually-consistent correspondence between D₀- and D₁-neighbourhoods — resolved to: $X \text{ n } Y \text{ n}$ and their `atomPair`-images $XPseq \text{ n } YPseq \text{ n}$ are *always genuine neighbourhoods* (never merely “mem-or- $\emptyset$ ”), on both sides, unconditionally
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** the vagueness resolved cleanly, with **no separate “mutual extension” hypothesis needed beyond NoMinimal on both sides** — a genuine (if small) new fact, not just transcription. Key discovery: `NeighborhoodSystem.NoMinimal.mem_ne_empty` (fully generic, placed right after `NoMinimal`’s own definition): `D.NoMinimal` forces $\neg D.mem \emptyset$, since applying `NoMinimal` at $X := \emptyset$ would demand a non-empty $Y \subseteq Y \cup Z = \emptyset$, impossible (`Set.union_empty_iff` then `Y.Nonempty.ne_empty`). Hence `X_ne_empty/Y_ne_empty`: `hXmem/hYmem`’s enumerated sets are never $\emptyset$ (direct corollary). Then the key transfer step — `X_eq_empty_iff_XPseq_eq_empty/Y_eq_empty_iff_YPseq_eq_empty`: collapsing (5)(d)’s $i = j$ inter-empty transfer facts (`X_inter_empty_iff_XPseq_inter_empty/YPseq_inter_empty_iff_Y_inter_empty` at $i = j = n$) through `Set.inter_self` gives *exactly* $X \text{ n } = \emptyset \leftrightarrow XPseq \text{ n } = \emptyset$ (resp. $Y \text{ n } = \emptyset \leftrightarrow YPseq \text{ n } = \emptyset$) for free, no new proof content beyond the substitution. Combining: `XPseq_ne_empty/YPseq_ne_empty` (never $\emptyset$, since their X/Y-side partner isn’t), then `XPseq_mem/YPseq_mem`: resolving (vi)(4)’s `XPseq_empty_or_mem/YPseq_empty_or_mem` disjunction against the just-proved non-emptiness gives $D_1.mem (XPseq \text{ n })/D_0.mem (YPseq \text{ n })$ unconditionally — completing the correspondence $X \text{ n } \leftrightarrow XPseq \text{ n } / Y \text{ n } \leftrightarrow YPseq \text{ n }$ as *always* a matched pair of genuine neighbourhoods on both sides, exactly what (vii)’s `DomainIso` assembly needs (mirroring `Theorem88a.lean`’s `Yidx_nonempty/Yidx_mem`, but derived very differently here — from the emptiness-transfer already in hand, rather than from an `idxSet`-style reflexivity trick). Zero sorry; whole-project lake build (3163 jobs) green; `#print axioms` on the headline theorems (`NoMinimal.mem_ne_empty`, `X_ne_empty`, `Y_ne_empty`, `XPseq_mem`, `YPseq_mem`) all give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the section’s baseline. **8.12(c)(vi) is now fully Pass, all of (1)–(7).**

Exercise 8.12(c)(vii)

- **Mathematical Target:** Part 7 of 7 — final assembly of (iv)/(v)/(vi)’s ingredients into the headline `DomainIso D0 D1` (`D0.Element  $\simeq$  D1.Element`), completing Exercise 8.12(c)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean` (in progress); umbrella — see sub-rows **8.12(c)(vii)(1)–(6)** below, mirroring how (c)(vi)(5)(c) was scoped before executing
- **Proof Notes:** scoped into 6 sub-parts 2026-07-04 (**8.12(c)(vii)(1)–(6)**, mirroring how (vi)(5)(c) was scoped before executing), then executed sub-part by sub-part, **all now Pass**. Adapted `Theorem88a.lean`’s `Iso`-section pattern (pushforward/pullback filter construction `toDprimeU/toD`, mutual-inverse + order-preservation) from *embedding an arbitrary D into a freshly-built D'* to *directly relating two pre-existing systems D₀/D₁* via the

already-proved $X \ n \leftrightarrow XPseq \ n / Y \ n \leftrightarrow YPseq \ n$ correspondence. The three gaps identified at scoping time were all resolved essentially as anticipated, **plus one genuinely new lemma discovered only during execution**: $XPseq_eq_Y_iff_X_eq_YPseq$, the two-*family* generalization of Theorem88a.lean’s `embed_eq_iff` (needed because `toD1/toD0`’s `up_mem` must rename a witness across the $X/XPseq$ vs. $Y/YPseq$ family boundary, unlike Theorem88a.lean’s single shared index family). Headline results: `toD1 : D0.Element → D1.Element`, `toD0 : D1.Element → D0.Element`, `domainIso812c : DomainIso D0 D1`, `isomorphic_812c : D0 ≅D D1`. See sub-rows for full detail, including a documented Lean auto-variable-inclusion gotcha (`def ... where` structures auto-include across all fields; plain `theorem := term / := by` do not) hit repeatedly throughout.

Exercise 8.12(c)(vii)(1)

- **Mathematical Target:** Add the covering/surjectivity hypotheses `hXcover : ∀ S, D0.mem S ↔ ∃ n, S = X n` and `hYcover : ∀ S, D1.mem S ↔ ∃ n, S = Y n` to the construction (mirroring Theorem88a.lean’s `hcover`), plus Scott’s zero-convention hypotheses `hX0 : X 0 = D0.master`/`hY0 : Y 0 = D1.master` (mirroring `he0`) — the missing hypotheses section `AtomPair`’s docstring already assumed but never formally declared

- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`

- **Proof Notes:** new section `Iso` opened, re-declaring the full `D0/D1/positivity/DiffClosed/NoMinimal/` variable list from section `AtomPair` plus the four new hypotheses `hXcover`, `hYcover`, `hX0`, `hY0` as variables. No proof content; pure declaration. **Lean gotcha hit and fixed:** a `theorem` whose *proof body* (but not its stated type) uses a variable-bound hypothesis does **not** get that hypothesis auto-included — Lean 4 only auto-includes variables that appear in the declaration’s own signature. Fixed downstream by adding explicit `include h1 ... hn in` immediately before the (docstring, then) theorem for every such proof-only dependency (see (vii)(2)).

Exercise 8.12(c)(vii)(2)

- **Mathematical Target:** `XPseq 0 = D1.master` and `YPseq 0 = D0.master`, given (1)’s `hX0/hY0`

- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`

- **Proof Notes:** mirrors Theorem88.lean’s `Yseq_zero_eq_master` argument via `splitChoice' _ isSplitSpec`: at `n = 0`, `atomPair`’s pairing is `(D0.master, D1.master)` regardless of sign sequence, so `hX0 : X 0 = D0.master` makes the X -sub-step’s `D0.master \ X 0 = ∅`, forcing (by `SplitSpec'`’s uniqueness-of-empty-difference clause) the split’s “−”-branch empty and its “+”-branch to swallow all of `D1.master`; `XPseq_zero` then follows by `Set.Subset.antisymm` against the already-proved `XPseq_subset_master` using `subset_XPseq` at the empty history (`Fin.elim0`). `YPseq_zero` repeats the argument one level deeper for the Y -sub-step, reusing `hunion1` from the X -sub-step’s computation and `hY0` for the second `SplitSpec'` application, closing via `subset_YPseq`. Both theorems’ proofs reference `hD0pos/hD0diff/hD1pos/hD1diff/hXmem/hYmem/hD0mne/hD1mne/hX0(/hY0)` only in the tactic block, not the stated type, so each needs an explicit `include ... in` line (placed *before* the theorem’s docstring — placing it *between* docstring and `theorem` causes a parser error, confirmed empirically) to pull those variables into scope. Axiom-audited: `[propext, Classical.choice, Quot.sound]`, matching the pre-existing `XPseq_subset_master` baseline (choice already unavoidable via `splitChoice'`).

Exercise 8.12(c)(vii)(3)

- **Mathematical Target:** The cross-parity specializations of `transfer_subset_combined/transfer_inter_eq_combined` needed for `up_mem/inter_mem`'s mixed cases: $X \text{ i} \subseteq Y \text{ pseq j} \leftrightarrow X \text{ pseq i} \subseteq Y \text{ j}$ (order) and an `exists_inter_index`-style pair of lemmas (mirroring `Theorem88a.lean`'s `exists_inter_index_of_dmem/_of_nonempty`) built from `X_inter_eq_iff_XPseq_inter_eq/YPseq_inter_eq_iff_Y_inter_eq` ((5)(d)) plus (1)'s `hXcover/hYcover`, for both the $D_0 \rightarrow D_1$ and $D_1 \rightarrow D_0$ directions
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `X_subset_YPseq_iff_XPseq_subset_Y/YPseq_subset_X_iff_Y_subset_XPseq` are direct specializations of `transfer_subset_combined` at the mixed indices $(2i, 2j+1)/(2i+1, 2j)$, using the same `Set.inter_eq_self_of_subset_right` bookkeeping as (5)(d)'s same-parity headline facts — zero new proof machinery, exactly as scoped. `exists_inter_index_X/exists_inter_index_Y` mirror `Theorem88a.lean`'s `exists_inter_index_of_dmem` (the “unwitnessed” `_of_nonempty` variant is **not** needed here — unlike `Theorem88a.lean`'s from-scratch `DprimeU`, D_0/D_1 are pre-existing systems whose own `inter_mem` axioms already take a direct membership witness, so no nonempty-to-witness bridge is required at this layer): given a $D_0.\text{mem}/D_1.\text{mem}$ witness that $X \text{ i} \cap X \text{ j}/Y \text{ i} \cap Y \text{ j}$ is itself a neighbourhood, `hXcover/hYcover` names it as $X \text{ m}/Y \text{ m}$, and (5)(d)'s `X_inter_eq_iff_XPseq_inter_eq(.mp)/YPseq_inter_eq_iff_Y_inter_eq(.mpr)` pushes the same equation across to `XPseq/YPseq`. All four theorems need `include ... in` (see (vii)(2)'s note on the auto-include gotcha) since their proofs use `hD0pos/hD0diff/hD1pos/hD1diff/hXmem/hYmem/hI` only in the tactic block. Axiom-audited: all four give $\subseteq \{\text{propext, Classical.choice, Quot.sound}\}$, matching the section baseline.

Exercise 8.12(c)(vii)(4)

- **Mathematical Target:** $\text{toD1} : D_0.\text{Element} \rightarrow D_1.\text{Element}$, the pushforward filter $\{T \mid \exists n, T = X \text{ pseq } n \wedge x.\text{mem } (X \text{ n})\}$, proved to satisfy all of `Element`'s axioms (`sub`, `master_mem`, `inter_mem`, `up_mem`)
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** `sub/master_mem/inter_mem` are immediate from `XPseq_mem/XPseq_zero/exists_inter_index_X`, direct transcription of `Theorem88a.lean`'s `toDprimeU`. `up_mem` needed one genuinely new lemma beyond (3)'s scoping: `XPseq_eq_Y_iff_X_eq_YPseq (j k) : XPseq j = Y k  $\leftrightarrow$  X j = YPseq k`, the two-family analogue of `Theorem88a.lean`'s `embed_eq_iff` — since `Theorem88a.lean`'s single enumeration `e` shares the *same* index across `e/Yidx`, its `embed_eq_iff` is one `embed_subset_iff` applied twice, but our two-family setup ($X/XPseq$ vs. $Y/YPseq$) needs *both* cross-parity order facts from (3) (`X_subset_YPseq_iff_XPseq_subset_Y` and `YPseq_subset_X_iff_Y_subset_XPseq`, applied at swapped index pairs) combined via `Set.Subset.antisymm` on each side. With that in hand, `up_mem`'s argument is: `hYcover` names the target $D_1.\text{mem}$ set as some $Y \text{ k}$; the cross-parity order fact turns $X \text{ pseq } i \subseteq Y \text{ k}$ into $X \text{ i} \subseteq Y \text{ pseq } k$; `x.up_mem` (on the D_0 side, via `YPseq_mem`) gives `x.mem (YPseq k)`; `hXcover` renames `YPseq k` as some $X \text{ j}$; `XPseq_eq_Y_iff_X_eq_YPseq` certifies $Y \text{ k} = X \text{ pseq } j$, closing the goal. Axiom-audited: `XPseq_eq_Y_iff_X_eq_YPseq/toD1` both give $\subseteq \{\text{propext, Classical.choice, Quot.sound}\}$, matching baseline.

Exercise 8.12(c)(vii)(5)

- **Mathematical Target:** $\text{toD0} : D_1.\text{Element} \rightarrow D_0.\text{Element}$, the symmetric pullback filter $\{S \mid \exists n, S = Y \text{ pseq } n \wedge y.\text{mem } (Y \text{ n})\}$, proved to satisfy all of `Element`'s axioms

- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** exact mirror of (4) with the two sides' roles swapped (`YPseq_mem/YPseq_zero/exists_inter_index_Y` for `sub/master_mem/inter_mem`; `YPseq_subset_X_iff_Y_subset_XPseq/hXcover/hYcover/(4)'s XPseq_eq_Y_iff_X_eq_YPseq` for `up_mem`, now used in its `.mp` direction rather than `.mpr/.symm` since the roles are swapped). Axiom-audited: $\subseteq \{\text{propxt}, \text{Classical.choice}, \text{Quot.sound}\}$, matching baseline.

Exercise 8.12(c)(vii)(6)

- **Mathematical Target:** `toD1/toD0` are mutually inverse and order-preserving/-reflecting, assembling `domainIso812c : DomainIso D0 D1` and the headline `isomorphic_812c : D0  $\cong^D$  D1`, completing Exercise 8.12(c) in full
- **Lean File:** `Scott1980/Neighborhood/Exercise812c.lean`
- **Proof Notes:** direct transcription of `Theorem88a.lean`'s `domainIso`'s `left_inv/right_inv/map_rel_iff'` fields (renamed `domainIso812c/isomorphic_812c` — plain `domainIso` already exists in `Theorem88a.lean` within the same `Scott1980.Neighborhood` namespace, a name clash only surfaced by the whole-project `lake` build, not the single-file build). `left_inv/right_inv` use (4)'s `XPseq_eq_Y_iff_X_eq_YPseq` at each of its two directions (`.mp/.mpr`, with an extra outer `.symm` chain on one side) to resolve “which index in the *other* family represents a given neighbourhood” — a genuinely two-*family* generalization of `Theorem88a.lean`'s single-family `embed_eq_iff` use. `map_rel_iff'` only ever compares two `XPseq`-witnesses against each other (never crossing families), so it needs just the ordinary same-family companion `X_eq_iff_XPseq_eq (i j) : X i = X j  $\leftrightarrow$  XPseq i = XPseq j` (one new lemma, direct antisymmetry corollary of `X_subset_iff_XPseq_subset` applied twice, exactly mirroring `Theorem88a.lean`'s own `embed_eq_iff`). **Lean gotcha, confirmed and documented for future work:** `def foo ... where field1 := term field2 := by tac ...` auto-includes any variable referenced *anywhere* across all its fields (term- or tactic-mode) as an implicit parameter of the whole declaration — but a plain `theorem foo := term/:= by tac` (not a `where`-structure) does **not** get this treatment and needs every used variable listed in an explicit `include ... in`, confirmed by `isomorphic_812c`'s own build failure (missing `hD0nomin/hD1nomin/X/Y` from its `include` list despite being literally written in its one-line term). Axiom-audited: `X_eq_iff_XPseq_eq/domainIso812c/isomorphic_812c` all give $\subseteq \{\text{propxt}, \text{Classical.choice}, \text{Quot.sound}\}$, matching baseline. Whole-project `lake` build (3163 jobs) green.

Exercise 8.12(d)

- **Mathematical Target:** Part 4 of 7 — effective refinement of (c): if D_0, D_1 are effectively given and (c)'s extension property is witnessed computably, the resulting order isomorphism is an `EffectiveIso`
- **Lean File:** — (not yet started; scoped 2026-07-04, stopping before executing, per this project's discipline for genuinely new pieces); umbrella — see sub-rows **8.12(d)(1)–(6)** below, mirroring how (c)(vii) was scoped before executing
- **Proof Notes:** Scoping investigation, comparing against `Theorem 8.8(b)`'s precedent (its own effective refinement of `8.8(a)`, 8 sub-parts across `Theorem88b.lean`–`Theorem88g.lean` ~2,400 lines) and against `Exercise812c.lean`'s actual `SplitSpec'/splitChoice'` design. Key finding — (d) is genuinely harder than `8.8(b)` in one specific respect, but also more tractable in another:

- *Harder*: Theorem 8.8(b)’s effective refinement only ever needs to split U’s side (Theorem 8.8(a)’s `atomU/Yidx` construction only ever calls `U_no_minimal`, never anything on the arbitrary D-side — D only needs its *index relations* decidable, via the fully generic `DAtomDecidable.lean`, already reusable as-is for **both** D_0 and D_1 here). Exercise 8.12(c)’s `xStep/yStep`, by contrast, split **both** sides alternately (`splitChoice' D1/splitChoice' D0`), so an effective refinement needs an *effective, computable replacement for NoMinimal’s splitting existential on both D_0 and D_1* — and unlike U, D_0/D_1 are *arbitrary* effectively-given systems with no special concrete structure (no interval/dyadic representation) to build an explicit `splitU`-style deterministic split from.
- *More tractable*: `exists_split`’s proof (`Exercise812c.lean` lines 226–258) shows the split witness `I, J` **never needs to relate to the probe set X_n beyond a nonemptiness match** ($A \cap X_n = \emptyset \leftrightarrow I = \emptyset$, $A \setminus X_n = \emptyset \leftrightarrow J = \emptyset$) — in the genuine-split case it is *any* `NoMinimal`-witnessed disjoint nonempty pair `Y, Z` of the target `B`, with no further constraint. This means an effective split doesn’t need to track *which* piece of `B` “belongs to” which piece of `A` — all of that cross-side bookkeeping is already handled entirely by the *transfer* lemmas (`transfer_dir/transfer*_combined`), independently of the split’s specific choice. So the needed new theorem is comparatively clean to *state*: “given a `ComputablePresentation` `P` of a `NoMinimal` system `E` and (the index of) some `P.mem`-witnessed `B`, computably/effectively produce indices `m, m'` with `P.X m, P.X m'` a valid `NoMinimal`-split of `B`” — plausible via **unbounded search** (`Nat.rfind`-style) over pairs `(m, m')`, checking the *decidable* predicate “`P.X m ∩ P.X m' = ∅` $\wedge$ `P.X m ∪ P.X m' = B`” (built from `interEq_computable/a` union-decider — nonemptiness is free, since `NoMinimal.mem_ne_empty` (8.12(c)(vi)(7)) already shows no `P.mem` set is ever $\emptyset$), **guaranteed to halt** because `NoMinimal`’s `Prop`-level existence guarantees at least one such pair is enumerated eventually. This is exactly the “unbounded search inside an r.e. predicate” idiom already used pervasively in Chapter 7–8 (e.g. Theorem 7.6’s `fixMap_isComputable`), and `Definition71.lean`’s own `ComputablePresentation.inter` docstring already flags this exact search ($\mu k. X_n \cap X_m = X_k$) as the *non-primitive-recursive* fallback its `inter` field is designed to avoid needing generically.

- **Design decision needed before executing (flagged, not resolved, pending user input)**: should (d) attempt the **fully generic** “`NoMinimal` + effectively given $\implies$ effective split via search” theorem above (real new math, extra effort, but then applies automatically to *any* effectively-given D_0/D_1 , potentially even letting (e)/(f) skip building bespoke concrete splits for `U/V`), or take the **safer, Theorem88.lean-style route**: generalize `xStep/yStep/atomPair/.../domainIso812c` over an **abstract hypothesis** “`splitX/splitY` are computable and satisfy `SplitSpec'`” (mirroring `Theorem88b.lean`’s “generalize over abstract `split`”), *deferring* “does such a split exist” to whoever instantiates the theorem — i.e. to (e)/(f), which would then need to build bespoke computable splits for `U` (largely reusable from Theorem 8.8(b)’s existing `SplitU.lean`) and `V` (new, but expected to be comparably easy given `V`’s neighbourhoods are already coarse dyadic-residue unions). **The safer route is recommended**: it mirrors this project’s established pattern of parametrizing over abstract hypotheses first and instantiating later, and avoids committing to the generic search theorem’s added risk/effort inside (d) itself (that theorem, if wanted, could always be added as a *separate*, later strengthening). Sub-parts below assume the safer route.

Exercise 8.12(d)(1)

- **Mathematical Target**: Generalize `Exercise812c.lean`’s `xStep/yStep/atomPair` (through `atomPair_disjoint/atomPair_fst_subset_master/atomPair_snd_subset_master`) over

abstract splitX : Set $\alpha \rightarrow$ Set $\beta \rightarrow$ Set $\alpha \rightarrow$ Set $\beta \times$ Set β / splitY : Set $\beta \rightarrow$ Set $\alpha \rightarrow$ Set $\beta \rightarrow$ Set $\alpha \times$ Set α hypotheses satisfying SplitSpec' (mirroring Theorem88b.lean's "6a")

- **Lean File:** Scott1980/Neighborhood/Exercise812d.lean (new)
- **Proof Notes: Scope adjustment, discovered during execution:** the original wording also listed XPseq/YPseq/combinedX/combinedY/toD1/toD0/domainIso812c as needing a parallel classical-abstract-split generalization here. This turns out to be unnecessary extra work — those are all downstream consequences of atomPair's invariant/disjointness/subset facts alone (never touching the split function or its SplitSpec' proof directly), so (d) (3)–(d) (6) build the *code-level* analogues (atomPairCode, XPseqCode/YPseqCode, computability, final EffectiveIso) directly atop this sub-part's atomPairG, without a redundant classical replica of the whole downstream chain first. Kept (d) (1) focused on the genuinely load-bearing recursive core. Implementation: xStepG/yStepG (literally xyStep splitX/(xyStep splitY _ _ _).swap — Exercise812c.lean's own xyStep/xyStep_disjoint_of_ne/SplitSpec'/splitChoice' layer was **already** split-agnostic, so only xStep/yStep themselves needed generalizing) plus their subset/disjointness lemmas (xStepG_fst_subset, xStepG_snd_subset, yStepG_fst_subset, yStepG_snd_subset, xStepG_disjoint_of_ne, yStepG_disjoint_of_ne, all taking hxSplit : SplitSpec' D₁ splitX/hySplit : SplitSpec' D₀ splitY directly instead of deriving them from NoMinimal via splitChoice'_isSplitSpec); atomPairG (recursive def, verbatim transcription of atomPair with splitChoice' D₁ hD₁nomin/splitChoice' D₀ hD₀nomin replaced by splitX/splitY); atomPairG_succ_eq/atomPairG_invariant/atomPairG_congr/xStepG_spec/atomPairG_fst_subset/atomPairG_snd_subset/atomPairG_fst_subset_master/atomPairG_snd_subset_master/atomPairG_disjoint, each a direct transcription of its Exercise812c.lean counterpart with splitChoice'_isSplitSpec D₁ hD₁nomin (a term) replaced by the hypothesis hxSplit/hySplit. **Bonus finding:** NoMinimal itself is no longer needed *anywhere* in this generalized layer — only SplitSpec' is ever used, so the abstraction actually **drops** a hypothesis relative to (c)'s original. Closed with a sanity-check corollary atomPairG_splitChoice_eq: instantiating splitX := splitChoice' D₁ hD₁nomin, splitY := splitChoice' D₀ hD₀nomin recovers atomPair exactly (by induction, atomPairG_succ_eq/atomPair_succ_eq unfold to the identical let-chain). **Lean gotcha hit:** atomPairG_congr initially forgot to omit the newly-introduced hySplit/hxSplit section variables (unused in its statement), causing a silent argument-shift at call sites (a bare splitX landing in hySplit's slot, "Type mismatch" against SplitSpec' D₀ splitY) — fixed by adding them to the omit ... in list. Axiom-audited: atomPairG_invariant/atomPairG_disjoint/atomPairG_fst_subset_master/atomPairG_snd_subset_master/atomPairG_splitChoice_eq all give $\subseteq$ {propxet, Classical.choice, Quot.sound}, matching the (c) baseline. Wired into Scott1980.lean. Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(2)

- **Mathematical Target:** Define what "splitX/splitY computable relative to presentations P₀, P₁" means
- **Lean File:** Scott1980/Neighborhood/Exercise812d.lean
- **Proof Notes:** IsComputableSplit {V W} (P : ComputablePresentation V) (Q : ComputablePresentation W) (split : Set $\alpha \rightarrow$ Set $\gamma \rightarrow$ Set $\alpha \rightarrow$ Set $\gamma \times$ Set γ): two index functions posIdx/negIdx : $\mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N}$ (indices of A, B, X_n in, index of the corresponding output in Q), each Nat.Primrec (on the Nat.pair n (Nat.pair m k) coding, matching RecDecidable₃'s convention) with an *exact* correctness spec (split (P.X n) (Q.X m) (P.X k)).1 = Q.X (posIdx n m k) (resp. .2/negIdx) — closer in shape to ComputablePresentation.inter's

primitive-recursive index function (exact equality) than to `IsComputableMap`’s r.e. *relation* (Definition 7.2), since a split is a genuine total function, not a semi-decidable membership test. **One structure serves both sides:** `IsComputableSplit P0 P1 splitX` and `IsComputableSplit P1 P0 splitY` (roles swapped) are both instances of the same fully generic $\{\alpha \ \gamma\}$ structure — no separate X/Y-flavoured version needed. Two trivial consequences included (`posIdx_mem/negIdx_mem`: both outputs are always genuine *W*-neighbourhoods, immediate from `Q.mem_X`). Needed `import Scott1980.Neighborhood.Definition71` explicitly (`ComputablePresentation` isn’t transitively re-exported by `Exercise812c.lean`’s own imports). Axiom-audited: both consequence lemmas depend on **no axioms at all** (fully constructive — no `Classical/propext/Quot.sound` needed, since they’re pure rewriting). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(3)

- **Mathematical Target:** The code-level two-sided atom recursion `atomPairCode`
- **Lean File:** — (not yet started); umbrella — see sub-rows **8.12(d)(3)(a)–(f)** below, re-scoped 2026-07-04 before executing (mirroring how (c)(vii) and (d) itself were scoped)
- **Proof Notes: Re-scoping investigation, done before writing any code, prompted by two discoveries while comparing against `Theorem88d.lean`’s precedent:**
 1. **A missing prerequisite.** `Theorem88d.lean`’s central design trick — never build a `Set`-valued split/step function; track an explicit presentation-index as state from the very first step, since there is no way to effectively recover “the” canonical index of an arbitrary `Set` — means `atomPairG`’s recursion needs **both** intersection *and* set-difference to stay effectively indexed at every step. But Scott’s `ComputablePresentation` (Definition 7.1) only requires the **intersection** relation/index (`inter/cons_computable`) to be computable — there is no analogous “diff index” primitive for `\`. `Theorem88d.lean` never needed one because `U/V` have bespoke, concrete diff constructions (`SplitU.lean`, bitmask XOR); for an *arbitrary* effectively-given `D0/D1` there is no such guarantee, so a new prerequisite hypothesis (mirroring `inter/cons_computable`’s shape, but for `\`) is needed before `atomPairCode` can be built at all.
 2. **The scale of the state machine itself.** The bulk of `Theorem88d.lean`’s ~1300 lines is not the recursion’s “happy path” but its **junk/decidable-emptiness tracking** (`atomUEmpty`, `datumDec`, freezing at a junk sentinel once a branch goes empty, `atomUCode_disjoint`’s restriction to non-junk branches) — needed because `SplitSpec`’s “direct” sub-step ($A \cap X_n / A \setminus X_n$) can genuinely be empty, unlike the “split” sub-step’s two outputs (never literally $\emptyset$, by `NoMinimal.mem_ne_empty`, (c)(vi)(7)). `atomPairG` alternates **two** interleaved sides (`xStep`’s direct-then-split on `D1`, `yStep`’s direct-then-split on `D0`), so a faithful `atomPairCode` needs this whole apparatus built — and kept mutually in sync — **twice**, not once.
 3. **A simplification found while analyzing the above (partial compensation):** decidability of the *split* sub-step’s own emptiness turns out to be **free**, not a separate hypothesis: `SplitSpec`’s defining clause $A \cap X_n = \emptyset \leftrightarrow (\text{split } A \ B \ X_n).1 = \emptyset$ means “is the split output empty” reduces *exactly* to “is the direct side’s intersection/difference empty” — i.e. once the direct-side deciders exist (`cons_computable` for $\cap$, the new hypothesis’s decider for $\setminus$), the split side’s decidability comes along for free via this *iff*, with no separate decidability field needed on `IsComputableSplit`.
- **Tentative sub-part breakdown (6 parts, pending confirmation):**

1. **(d)(3)(a)** — `IsComputableDiff {V} (P : ComputablePresentation V)`: the missing prerequisite from finding 1 above, mirroring `ComputablePresentation`’s own `inter/cons_computable` pair but for $\setminus$ — a primitive-recursive `diffIdx : $\mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N}$ with diffIdx_spec : ($\exists k, X k = X n \setminus X m$) $\rightarrow X (diffIdx n m) = X n \setminus X m$ (mirroring inter_spec’s shape exactly), plus a RecDecidable2-style decider for “ $X n \setminus X m$ is a genuine neighbourhood” (mirroring cons_computable, needed per finding 3 to get the split-side’s decidability for free). One structure serves both P_0 and P_1 symmetrically, same design as IsComputableSplit.`
2. **(d)(3)(b)** — the per-depth state representation: a `Nat`-code packing (in `Theorem88d.lean`’s `packState` style) both sides’ current presentation-index (D_0 -side index into P_0 , D_1 -side index into P_1) plus a junk/non-junk flag per side, and the X -sub-step’s state transition (intersect/diff the D_0 -side index directly by n via $P_0.inter/(a)$ ’s `diffIdx`, split the D_1 -side index via (2)’s `IsComputableSplit`) as a single `Nat.Primrec` step function.
3. **(d)(3)(c)** — the Y -sub-step’s state transition (symmetric: intersect/diff the D_1 -side index directly by n , split the D_0 -side index), combined with (b) into the full $n \rightarrow n + 1$ transition `atomPairCodeState`, mirroring `Theorem88d.lean`’s `atomUCodeState/atomStep`.
4. **(d)(3)(d)** — per-step correctness: whenever the recorded state is non-junk, the packed indices’ $P_0.X/P_1.X$ values literally equal `atomPairG`’s corresponding component at that depth, mirroring `genAtom_atomUCode`.
5. **(d)(3)(e)** — the junk invariant: once junk, a side stays junk forever (mirroring `atomUEmpty_mono`); non-junk states are always genuine D_0/D_1 -neighbourhoods (mirroring `atomUCode_mem`).
6. **(d)(3)(f)** — disjointness: for two sign-sequences disagreeing below depth n with *both* still non-junk at depth n , the corresponding indexed sets are disjoint on both sides, mirroring `atomUCode_disjoint`.

Exercise 8.12(d)(3)(a)

- **Mathematical Target:** `IsComputableDiff`: a computable “diff index” hypothesis mirroring `ComputablePresentation`’s `inter/cons_computable` pair, but for $\setminus$ (the missing prerequisite Scott’s Definition 7.1 doesn’t provide)
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean`
- **Proof Notes:** `diffIdx : $\mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N}$, Nat.Primrec (diffIdx_primrec), with diffIdx_spec : ($\exists k, X k = X n \setminus X m$) $\rightarrow X (diffIdx n m) = X n \setminus X m$ (mirroring inter_spec exactly) plus diff_computable : RecDecidable2 (fun n m => $\exists k, X k = X n \setminus X m$) (mirroring cons_computable’s role for $\cap$). One generic structure serves both P_0 and P_1 , same design as (d)(2)’s IsComputableSplit. Added a derived (not structure-bundled) consequence, diff_exists_iff_ne_empty, showing that under DiffClosed + NoMinimal the structure’s existential phrasing “ $X n \setminus X m$ is a genuine neighbourhood” coincides with “ $X n \setminus X m$ is non-empty” (via DiffClosed’s $X \setminus Y = \emptyset \vee \text{mem}(X \setminus Y)$ dichotomy plus NoMinimal.mem_ne_empty/surj) — kept off the structure itself (mirroring how DiffClosed/NoMinimal are separate hypotheses elsewhere), but available for (d)(3)(b)–(f) to read diff_computable as a genuine emptiness decider directly. Needed open Domain.Recursive added to the file (for RecDecidable2, not previously referenced in this file). Axiom-audited: diff_exists_iff_ne_empty gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the (c)/(d) baseline. Whole-project lake build (3164 jobs) green, zero sorry.`

Exercise 8.12(d)(3)(b)

- **Mathematical Target:** The X-sub-step’s code-level state transition
- **Lean File:** Scott1980/Neighborhood/Exercise812d.lean
- **Proof Notes: Scope simplification, discovered during execution:** the per-depth state packs both sides’ current presentation-index plus a **single shared** junk/non-junk flag (`packState2 idx0 idx1 junk`) — *not* “one per side” as originally tentatively scoped, since (d)(1)’s own `atomPairG_invariant (ihAB)` already proves the two sides go empty *together* at every depth, so a per-side flag would always just duplicate the other. Built the extracted direct-refinement deciders first (`existsInterDec/emptyInterDec` from `cons_computable`, `existsDiffDec/emptyDiffDec` from (a)’s `IsComputableDiff.diff_computable`, each via the `Classical.choice`-extraction + `isOne`-wrapping pattern mirroring `Theorem88d.lean`’s `datumDec`), plus the connecting lemmas `existsInterDec_eq_zero_iff/existsDiffDec_eq_zero_iff` (relating the raw “consistency/exists” deciders to genuine emptiness, via `IsPositive+NoMinimal` for $\cap$ and (a)’s `diff_exists_iff_ne_empty` for $\setminus$). Then `xSubStep`: a single `Nat.Primrec` function of a packed `w = pair n (pair b1 s)` argument (mirroring `atomStep`’s `w = pair k (pair y state)` convention), refining D_0 ’s index directly (`P_0.inter/hDiff0.diffIdx`, selected by bit `b1`) and D_1 ’s index via the matching branch of `hSplitX.posIdx/negIdx`, freezing both at sentinel 0 the moment either the incoming state was already junk or the direct refinement is found empty. `primrec_xSubStep` assembled compositionally exactly mirroring `primrec_atomStep`’s pattern (a chain of `haves` building up `Nat.Primrec` for each sub-expression, finished by `.of_eq` unfolding the `let-chain`). Axiom-audited: all of `existsInterDec_eq_zero_iff/existsDiffDec_eq_zero_iff/emptyInterDec_eq_one_iff/emptyDiffDec_eq_one_iff/primrec_xSubStep` give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (the `Classical.choice` is purely in *naming* the already-primitive-recursive extracted deciders, exactly like `datumDec`’s own precedent). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(3)(c)

- **Mathematical Target:** The Y-sub-step’s code-level state transition, combined into the full `atomPairCodeState`
- **Lean File:** Scott1980/Neighborhood/Exercise812d.lean
- **Proof Notes:** `ySubStep`, symmetric to (b)’s `xSubStep` (intersect/diff the D_1 -side index directly against $P_1.X\ n$, split the D_0 -side index via `hSplitY : IsComputableSplit P_1 P_0 splitY`), reusing the *same* packed-argument projections `xwN/xwB1/xwS` unchanged (pure $\mathbb{N}$ -arithmetic, not tied to X). Composed with `xSubStep` into the full $n \rightarrow n + 1$ transition `atomPairStep` (one `xSubStep` with bit `rem % 2`, then one `ySubStep` with bit `(rem / 2) % 2`, at the same depth, then `rem / 4` peels both consumed bits — the bit-source `k` now supplies **two** bits per depth, since `atomPairG`’s $\delta : \mathbb{N} \rightarrow \text{Bool} \times \text{Bool}$ packs an (X, Y) -sub-step bit pair at every depth). Introduced a fresh outer pairing `packStateC (rem s)` wrapping the persistent bit-source remainder around (b)’s two-sided `packState2` triple; `pcN/pcT` extract the outer $(\text{depth}, \text{state})$ pair from the `Nat.Primrec.prec`-mandated `w = pair k (pair n state)` convention (`k` itself unused in the step body, exactly as `Theorem88d.lean`’s own `k` is unused inside `atomStep` — only present because that is how `Nat.Primrec.prec`’s recursor is shaped). `atomPairCodeState` assembles the full recursion via `Nat.Primrec.prec`, mirroring `atomUCodeState` exactly; `atomPairIdx0/atomPairIdx1/atomPairJunk` are the depth- n , bit-source- k projections (mirroring `atomUPos/atomUNeg/atomUCode`), each with a `Nat.Primrec`-ness lemma. No correctness-against-`atomPairG` claim yet — that is (d)(3)(d)’s job. **Lean gotcha hit:** initially tried to reuse `Theorem88d.lean`’s own `wY/wState` projections by name, but

`Exercise812d.lean` does not import `Theorem88d.lean` (nor should it — that file is about the *unrelated* U/D single-sided construction) — fixed by defining local `pcN/pcT` aliases over the already-available `xwN/xwB1/xwS`. No general “divide by a constant” primitive existed in `Recursive.lean` for `rem / 4` — built it from two `primrec_div2` applications plus `Nat.div_div_eq_div_mul`. Axiom-audited: `primrec_ySubStep/primrec_atomPairStep/primrec_atomPairCodeState/primrec_atomPairIdx0/primrec_atomPairIdx1/primrec_atomPairJunk` all give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the (b) baseline. Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(3)(d)

- **Mathematical Target:** Per-step correctness of `atomPairCodeState` against `atomPairG`
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean`
- **Proof Notes:** whenever the recorded state is non-junk, the packed indices’ $P_0.X/P_1.X$ values literally equal `atomPairG`’s corresponding component at that depth, mirroring `genAtom_atomUCode`. `deltaPair k : N → Bool × Bool` reads the two-bits-per-depth sign sequence off bit-source k ($(k / 4 \wedge i) \% 2$ for `.1`, $(k / 4 \wedge i / 2) \% 2$ for `.2`), matching how `atomPairStep` peels bits from `rem`. Built an *unconditional* per-step algebra layer first — `xSubStep_junk_eq/xSubStep_idx0_eq/xSubStep_idx1_eq` (and `ySubStep` counterparts) describe the sub-steps’ junk flag and both output indices for an arbitrary input state and bit, no side-hypotheses needed at all (`IsComputableSplit`’s `posIdx_spec/negIdx_spec` and `IsComputableDiff`’s `diffIdx_spec` are already unconditional). `junk_eq_zero_of_selectFn_eq_zero` (a 1-flag is frozen forever through `selectFn junk 1 _`) gives `atomPairJunk_eq_zero_of_succ` (junk propagates backward down the recursion, purely algebraically, no induction). Combined with `selectFn_one_eq_zero_iff` and fresh bridge lemmas `interIdx_eq_of_empty_zero/diffIdx_eq_of_empty_zero` (connecting `emptyInterDec/emptyDiffDec = 0` to genuine `Set` (in)equality), gives `xSubStep_correct/ySubStep_correct`: given matching previous indices and a non-junk output, the next indices match `xStepG/yStepG` exactly (case-split on the bit via `by_cases hb : b = true`, discharging `if b then _ else _` with `simp only [hb, if_true]/simp only [hb, Bool.false_eq_true, if_false]`). `atomPairCodeState_correct` is the main induction mirroring `genAtom_atomUCode`’s shape: base case reduces to $P_0.\text{masterIdx_spec}/P_1.\text{masterIdx_spec}$ via `simp [atomPairCodeState, atomPairBase, stateBase2]`; inductive step derives the previous depth’s junk-freeness via `atomPairJunk_eq_zero_of_succ`, extracts the two bits via `Nat.mod_two_eq_zero_or_one` matched against `deltaPair`, derives the intermediate (X-substep-only) state’s junk-freeness via `ySubStep_junk_eq + junk_eq_zero_of_selectFn_eq_zero` directly (no separate induction), then chains `xSubStep_correct` into `ySubStep_correct` to land on `atomPairG_succ_eq`’s RHS. **Lean gotchas:** a single combined `unfold ... at h1 h2` fails hard if a name doesn’t occur in *every* listed location — split into per-hypothesis `unfold` calls; explicit (non-`{}`) section variables mean a bare lemma `hjunk` mis-binds `hjunk` to the first positional arg — fixed with named argument (`h := hjunk`); `simp only [hb]` alone (for `hb : ¬ b = true`) rewrites the `Bool` variable `b` to the literal `false` but does not by itself collapse the resulting `if false = true then _ else _` — needed the explicit `Bool.false_eq_true/if_false` (resp. `if_true` in the positive branch) additions. Axiom-audited: all new theorems give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (the `Classical.choice` is inherited ambient `Set/NeighborhoodSystem` Prop-level reasoning, matching every other correctness-style theorem in this file, e.g. `xStepG_snd_subset` — not introduced fresh). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(3)(e)

- **Mathematical Target:** The junk invariant and validity of `atomPairCodeState`
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean`
- **Proof Notes:** once junk, a side stays junk forever (mirroring `atomUEmpty_mono`); non-junk states are always genuine D_0/D_1 -neighbourhoods (mirroring `atomUCode_mem`). Turned out much smaller than $(d)(3)(d)$: the hard direction (“junk propagates *backward*”) was already `atomPairJunk_eq_zero_of_succ` from $(d)(3)(d)$, so `atomPairJunk_mono` (forward propagation) is literally its contrapositive, needing only a fresh boundedness fact `atomPairJunk_le_one` (`atomPairJunk  $\in$  {0,1}` always, via induction + a small general helper `selectFn_le_one :  $c \leq 1 \rightarrow a \leq 1 \rightarrow b \leq 1 \rightarrow \text{selectFn } c \ a \ b \leq 1$`) to convert $\neq 0$ into $= 1$. “Validity” (`atomPairIdx0_mem/atomPairIdx1_mem`) is fully *unconditional* (no junk hypothesis needed) since `ComputablePresentation.mem_X` guarantees every index of P_0/P_1 is a genuine neighbourhood regardless of the recursion’s junk flag — one-line `P0.mem_X/P1.mem_X` applications. **Lean gotcha:** the first attempt at `atomPairJunk_le_one`’s successor case (ad hoc `rcases/simp/omega` directly on the doubly-nested `selectFn` expression) hit a `whnf` deterministic timeout — fixed by proving `selectFn_le_one` once and chaining three applications of it, never letting `omega/rcases` see the nested selector expression at all. Axiom-audited: `atomPairJunk_le_one/atomPairJunk_mono` give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$; `atomPairIdx0_mem/atomPairIdx1_mem` give the smaller $\subseteq \{\text{Classical.choice}\}$; `selectFn_le_one` gives $\subseteq \{\text{propext}, \text{Quot.sound}\}$. Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(3)(f)

- **Mathematical Target:** Disjointness of `atomPairCodeState` across disagreeing, non-junk sign-sequences
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean`
- **Proof Notes:** for two sign-sequences disagreeing below depth n with *both* still non-junk at depth n , the corresponding indexed sets are disjoint on both sides, mirroring `atomUCode_disjoint`. Completes 8.12(d)(3). Turned out almost entirely free: unlike `Theorem88d.lean` (no free-standing Set-level disjointness fact to transfer, so `atomUCode_disjoint` reproves disjointness *by induction* at the code level), the genuine mathematical content — `atomPairG_disjoint` — was already proved back in $(d)(1)$. `atomPairCodeState_disjoint` is a pure transfer lemma: apply $(d)(3)(d)$ ’s `atomPairCodeState_correct` to both bit-sources (rewriting each side’s indexed set as the corresponding `atomPairG` component), then hand off to `atomPairG_disjoint`. Needed a fresh section `AtomPairCorrect3` bringing back $(d)(1)$ ’s full hypothesis list (`SplitSpec'` for `splitX/splitY`, `IsPositive/DiffClosed` for D_0/D_1 , `Nonempty` masters) alongside $(d)(3)$ ’s own computability hypotheses (`IsComputableDiff/IsCo` — the two hypothesis sets are logically independent and both genuinely needed here. **Lean gotcha:** the extra hypotheses only appear inside the proof term (feeding `atomPairG_disjoint`), never in the theorem’s own stated type, so Lean’s auto-bound-variable mechanism wouldn’t pull them in automatically — fixed with an explicit `include ... in` immediately before the theorem (same idiom already used earlier in this file before `atomPairG_invariant`). Axiom-audited: `atomPairCodeState_disjoint` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$. Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)

- **Mathematical Target:** `XPseqCode/YPseqCode`, the code-level union constructions

- **Lean File:** — (not yet started); umbrella — see sub-rows **8.12(d)(4)(a)–(d)** below, re-scoped 2026-07-04 before executing (mirroring how (c)(vii), (d), and (d)(3) were all scoped before their own code)
- **Proof Notes: Re-scoping investigation, done before writing any code, comparing against Theorem88d.lean’s YseqCode/unionUX precedent and Approximable.lean/Theorem88n.ofIso precedent:**
 1. **A missing prerequisite, structurally different from (d)(3)(a)’s.** Theorem88d.lean’s `unionUX n m := appendCode (canonCode n) (canonCode m)` is **bespoke to U**: its codes are literal lists of rational intervals, freely concatenable, and `U_mem_union_` shows the union of *any* two U-neighbourhoods is unconditionally again a U-neighbourhood. Neither fact generalizes: Scott’s `ComputablePresentation` (Definition 7.1) gives an intersection index (`inter`) because `NeighborhoodSystem.inter_mem` makes intersection a *primitive* closure property — there is no analogous union primitive, because `V.mem` is **not** assumed closed under union at all. `Exercise812c.lean`’s `XPseq_mem/YPseq_mem` (already `Pass`, (c)(vii)) show the specific growing unions built by this construction *are* always genuine D_1/D_0 -neighbourhoods, but only via a bespoke `NoMinimal/SplitSpec` argument giving mere `Prop`-level existence (`P.surj`) of an index — not an effective way to compute one. So, exactly as (d)(3)(a) needed a fresh `IsComputableDiff` because Definition 7.1 has no diff-index primitive, (d)(4) needs a fresh prerequisite because Definition 7.1 has no union-index primitive either.
 2. **The union sizes match deltaPair’s existing base-4 convention.** `XPseq n = $\bigcup \delta' : \text{Fin } n \rightarrow \text{Bool} \times \text{Bool}$, ... unions over 4^n sign-pair-sequences (not 2^n as in Theorem88d.lean’s single-sided YseqCode), and YPseq n unions over an extra bx : Bool factor on top, i.e. $2 \cdot 4^n$. Conveniently, $i < 4^n \leftrightarrow$ a length- n prefix of bit-pairs is exactly (d)(3)(d)’s already-built deltaPair convention $((k / 4^i) \% 2 / (k / 4^i / 2) \% 2)$ — no new bit-source encoding needed, and (d)(1)’s atomPairG_congr already shows the depth- n value never depends on bits beyond position n , so extending a length- n prefix $i < 4^n$ to a full bit-source (e.g. literally k := i, padding implicitly with (false, false)) is immaterial — no fresh code-level congruence lemma is needed beyond what (d)(1) already proved at the classical atomPairG level.`
 3. **A classical generalization (d)(1)’s docstring explicitly deferred into this sub-part.** `Exercise812c.lean`’s `XPseq/YPseq` are hardcoded to `xStep/atomPair` (the `splitChoice`’-based, non-abstract construction) — (d)(1)’s docstring flags this exactly (“the original scoping listed `XPseq/YPseq/...` as also needing a parallel classical-abstract-split generalization ... (d)(3)–(d)(6) can build the code-level analogues ... directly on top of `atomPairG`”). Mirroring Theorem88d.lean’s own two-layer pattern (code-level `atomUCode/YseqCode` and the classical anchor `genAtom`, linked by `atomUCode_eq_genAtomYseqCode`), the cleanest route is a light, mechanical `XPseqG/YPseqG` (verbatim transcriptions of `XPseq/YPseq` over abstract `splitX/splitY`, exactly as (d)(1) transcribed `atomPair` into `atomPairG`) with their own `mem/zero/subset` facts transcribed from `XPseq_mem/XPseq_zero/etc.` — giving (d)(3)–(d)(6) a `Set`-level anchor to connect `XPseqCode` back to, without needing the original `splitChoice`’-hardcoded `XPseq` at all.
 4. **A downstream simplification found while investigating (d)(6) (does not reduce (d)(4)’s own scope, but bounds it and affects sub-part boundaries below):** `Approximable.lean`’s `ofIso` (**Theorem 2.7** — *any* domain isomorphism $e : V_0.\text{Element} \simeq_o V_1.\text{Element}$ induces an `ApproximableMap` $V_0 \rightarrow V_1$ choice-free) plus Theorem88n.lean’s already-proven precedent (`isoInj := ofIso (domainIsoCode`

P), reducing `IsComputableMap` to a raw-index inclusion test) strongly suggest (d)(6)'s `EffectiveIso.toMap/.invMap` should be `ofIso domainIso812c/ofIso domainIso812c.symm` directly, rather than re-deriving bespoke `ApproximableMaps` that duplicate `toD1/toD0`'s `up_mem` reasoning from scratch. **Crucial difference from Theorem88n.lean:** there, D/D' share *one* index family via a literal primitive-recursive involution `eIdx`, collapsing `isoInj`'s relation to a single reindexed `incl_computable` query with no search at all. Here, D_0/D_1 have genuinely *independent* index families (P_0, P_1) , so `(ofIso domainIso812c).rel (P0.X n) (P1.X m)` unfolds (via `toD1`'s definition and `V.principal`) to $\exists n', P_1.X m = XPseq\ n' \wedge P_0.X n \subseteq P_0.X n'$ — genuinely needing `XPseq n'`'s P_1 -index (i.e. `XPseqCode n'`) to reduce “ $P_1.X m = XPseq\ n'$ ” to something checkable. So `ofIso` simplifies (d)(6)'s *assembly* (no bespoke `ApproximableMap` axioms to re-prove) but does **not** remove (d)(4)'s core deliverable. **Correction (2026-07-05, (d)(5)'s scoping):** the specific claim above that `ofIso domainIso812c` is the right map to make computable is **wrong** — `domainIso812c`'s `XPseq/YPseq` are hardcoded to the classical, non-computable `splitChoice'`, disconnected from this track's effective `splitX/splitY`; (d)(5) needs a *fresh* order-iso built directly on `atomPairG/XPseqCode/YPseqCode` instead (see (d)(5)'s row, finding 1, for the full correction). The $\exists n', P_1.X m = [...] n' \wedge P_0.X n \subseteq P_0.X n'$ unfolding shape and “`XPseqCode/YPseqCode` get consumed” punchline above are otherwise directionally correct, once `XPseq n'` is replaced by `P1.X (XPseqCode n')`.

- **Design decision needed before executing (flagged, not resolved, pending user input — same fork as (d)'s own docstring, now recurring for $\cup$ instead of the effective split):** mirroring (d)(3)(a)'s `IsComputableDiff`, should the new union prerequisite be (a) an **abstract hypothesis** `IsComputableUnion` (mirroring `IsComputableDiff`'s shape: `unionIdx : $\mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N}$, Nat.Primrec , unionIdx_spec : $(\exists k, X\ k = X\ n \cup X\ m) \rightarrow X\ (\text{unionIdx}\ n\ m) = X\ n \cup X\ m$, plus a RecDecidable_2 existence-decider), deferred to instantiation exactly like IsComputableSplit/IsComputableDiff were; or (b) derived via unbounded search (Nat.rfind), since the specific unions arising in this fold are already known non-empty/genuine by NoMinimal/XPseq_mem, mirroring (d)'s own flagged-but-declined generic-search alternative. The abstract-hypothesis route is recommended, for the same reasons (d)'s docstring gave: consistent with this project's established pattern, and defers “does U/V actually admit an effective union index” to whoever instantiates at (e)/(f).`
- **Tentative sub-part breakdown (4 parts, pending confirmation):**
 1. (d)(4)(a) — `IsComputableUnion {V} (P : ComputablePresentation V)`: the missing prerequisite from finding 1, mirroring (d)(3)(a)'s `IsComputableDiff` shape exactly but for $\cup$ (one generic structure, reused for both P_0 and P_1 , same design as `IsComputableSplit/IsComputableDiff`).
 2. (d)(4)(b) — `XPseqG/YPseqG`: the classical `Set`-level generalization of `Exercise812c.lean`'s `XPseq/YPseq` over abstract `splitX/splitY` (finding 3), transcribing `XPseq_mem/XPseq_zero/YPseq_mem/YPseq_zero` verbatim onto the abstracted definitions — expected genuinely light/mechanical, per (d)(1)'s own docstring assessment, so bundled as one sub-part covering both sides.
 3. (d)(4)(c) — `XPseqCode`: the X-side fold (`XFoldStep/XFold`, mirroring `yFoldStep/yFold` over $i < 4^n$ using `deltaPair/(a)'s unionIdx` instead of $2^n/\text{unionUX}$) plus its closed-form membership characterization (mirroring `mem_UX_YseqCode_iff`) and the link back to (b)'s `XPseqG` (mirroring `atomUCode_eq_genAtomYseqCode`).
 4. (d)(4)(d) — `YPseqCode`: the Y-side fold, symmetric to (c) but with the extra `bx`

: Bool union layer ($2 \cdot 4^n$ total, an outer 2-way union of two inner 4^n -folds) plus its closed-form characterization and link to (b)’s YPseqG.

Exercise 8.12(d)(4)(a)

- **Mathematical Target:** `IsComputableUnion`: a computable “union index” hypothesis mirroring `ComputablePresentation`’s `inter/cons_computable` pair, but for $\cup$ (the missing prerequisite Scott’s Definition 7.1 doesn’t provide, and `Theorem88d.lean`’s `unionUX` doesn’t generalize past)
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean`
- **Proof Notes:** direct structural mirror of (d)(3)(a)’s `IsComputableDiff`, but for $\cup$ instead of $\setminus$: `IsComputableUnion` `P` bundles a primitive-recursive `unionIdx :  $\mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N}$` with `unionIdx_spec :  $(\exists k, X\ k = X\ n \cup X\ m) \rightarrow X\ (\text{unionIdx}\ n\ m) = X\ n \cup X\ m$` (mirroring `inter_spec` exactly) plus `union_computable :  $\text{RecDecidable}_2\ (\text{fun } n\ m \Rightarrow \exists k, X\ k = X\ n \cup X\ m)$` (mirroring `cons_computable`). One generic structure serves both `P0` and `P1`. Also added `NeighborhoodSystem.UnionClosed` (the $\cup$ analogue of `Exercise812c.lean`’s `DiffClosed`, but simpler — no “-or- $\emptyset$ ” branch needed, since a union of two neighbourhoods is never empty whenever either side isn’t) and a bonus corollary `IsComputableUnion.union_exists`, showing that under `UnionClosed` the existential in `unionIdx_spec` is unconditionally satisfiable (`P.surj` applied to `hunion (P.mem_X n) (P.mem_X m)`) — simpler than `IsComputableDiff.diff_exists_iff_ne_empty` since there’s no dichotomy to derive, just a plain existence fact. Kept off the structure itself, same design rationale as `DiffClosed/NoMinimal` being separate from `ComputablePresentation` elsewhere in this file; `docstring` explicitly notes the eventual (d)(4)(c)/(d) instantiation is expected to discharge `unionIdx_spec`’s hypothesis directly from `XPseq_mem/YPseq_mem`-style facts specific to the atoms in play, not from a blanket `UnionClosed` on all of `D`. No Lean gotchas — a clean, direct transcription. Axiom-audited: `IsComputableUnion.union_exists` depends on **no axioms at all** (fully constructive — even better than `IsComputableDiff.diff_exists_iff_ne_empty`, which needs the ambient `Classical/propext/Quot.sound` footprint via `DiffClosed`’s dichotomy). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(b)

- **Mathematical Target:** originally scoped as `XPseqG/YPseqG` (a classical `Set`-level generalization of `XPseq/YPseq` over abstract `splitX/splitY`); **re-scoped during execution** (see below) to `NeighborhoodSystem.mem_union_of_mem`, the actual prerequisite (d)(4)(c)/(d)’s folds need
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean`
- **Proof Notes:** **Scope simplification, discovered during execution (documented in-file as a docstring, mirroring (d)(1)’s own precedent for flagging such findings):** the originally-planned `XPseqG/YPseqG` turns out to be both unnecessary *and* the wrong shape. `XPseq_mem (Exercise812c.lean)` is proved via the heavy `combinedX/combinedY/transfer_inter_empty_combined` detour (≈ 1000 lines), which exists to identify `XPseq n` with *Scott’s specific* recovered neighbourhood (relating its emptiness back to `X n`’s) — but the fold only needs the much weaker, purely local fact that a *finite growing union of already-mem pieces stays mem*. That’s available directly from hypotheses already in scope everywhere in this file: `Exercise812c.lean`’s generic `union_mem_or_empty` (from `IsPositive+DiffClosed` alone, proved via the De Morgan identity $X \cup Y = M \setminus ((M \setminus X) \cap (M \setminus Y))$), giving

the dichotomy $X \cup Y = \emptyset \vee D.\text{mem } (X \cup Y)$ composed with one line ruling out $\emptyset$ whenever both inputs are *already* `mem` (hence already non-empty, via `NoMinimal.mem_ne_empty`): $X \cup Y \supseteq X \neq \emptyset$ rules out the dichotomy’s empty branch outright. New lemma: `NeighborhoodSystem.mem_union_of_mem {D} (hpos) (hdiff) (hnomin) {X Y} (hX : D.mem X) (hY : D.mem Y) : D.mem (X ∪ Y)`, one line: `(union_mem_or_empty hpos hdiff (Or.inr hX) (Or.inr hY)).resolve_left fun h => hnomin.mem_ne_empty hX (Set.subset_eq_empty Set.subset_union_left h)`. This is exactly what (d)(4)(c)/(d)’s folds use to discharge `IsComputableUnion.unionIdx_spec`’s existential hypothesis at every step, since each half-step atom folded in is unconditionally `P.mem_X`-genuine (`ComputablePresentation.mem_X` is total, regardless of code-level “junk” — cf. `atomPairIdx0_mem/atomPairIdx1_mem`, (d)(3)(e)), so the running union of finitely many such atoms is genuine by a one-line induction via this lemma alone — no need to relate anything back to `XPseq/YPseq`, and no need to redo (d)(1)’s abstraction over `splitX/splitY` a second time. Axiom-audited: `Scott1980.Neighborhood.NeighborhoodSystem.mem_union_of_mem` depends on `[propext, Classical.choice, Quot.sound]` (the ambient ubiquitous baseline, inherited via `union_mem_or_empty`’s own classical case-splitting). Whole-project lake build green, zero sorry.

Exercise 8.12(d)(4)(c)

- **Mathematical Target:** `XPseqCode`, the code-level X-side union fold, with closed-form correctness
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean`
- **Proof Notes:** builds `XPseqCode` purely at the code level (no reference to `Exercise812c.lean`’s classical `XPseq/atomPair`, nor even to (d)(1)’s classical `atomPairG` — see (d)(4)(b)’s scope note for why that classical detour was unnecessary). **The half-step atom:** `xPseqAtomState n i` re-runs `xSubStep` on the depth- n two-sided state at bit-source $i < 4^n$ with the X-sub-step’s bit forced to 1 (the “+”/true branch `XPseq`’s classical definition always selects); `xPseqAtomIdx/xPseqAtomJunk` harvest `stateIdx1/stateJunk` of that. Closed forms `xPseqAtomJunk_eq (= selectFn (atomPairJunk n i) 1 (emptyInterDec P0 (idx0, n)))` and `xPseqAtomIdx_eq` (when non-junk, = `hSplitX.posIdx idx0 idx1 n`) come directly from (d)(3)(b)’s `xSubStep_junk_eq/xSubStep_idx1_eq` specialized at `b1 := 1`. `xPseqAtomIdx_mem` (the atom is always D_1 -genuine, junk or not) is free from `ComputablePresentation.mem_X`’s totality — no hypotheses needed, exactly like (d)(3)(e)’s `atomPairIdx1_mem`. **The fold:** `XFoldStep/XFold` mirror `Theorem88d.lean`’s `yFoldStep/yFold` verbatim in shape (packed (found, code) accumulator, `selectFn`-driven skip-if-junk/union-else), folding over $i < 4^n$ using (d)(4)(a)’s `hUnion1.unionIdx` in place of `unionUX` — genuinely *simpler* to make primitive-recursive than `yFoldStep` since there’s no “+2ⁿ”/“+1” bit-forcing index arithmetic needed (our half-step atom already reads directly off $i < 4^n$, one level, not `Theorem88d.lean`’s two-tier $n+1/i+2^n$ encoding). **Correctness, conditional on “found” throughout** (mirroring `yFold_found_iff/yFold_mem_iff`’s own phrasing exactly): `XFold_found_le_one/XFold_found_iff` are direct, unconditional mirrors (no genuineness tracking needed for the flag itself). `XFold_mem_of_found` is genuinely new content beyond `Theorem88d.lean`’s precedent (there, `unionUX`’s output is unconditionally genuine since U is unconditionally union-closed — not so here): proved by induction, discharging `hUnion1.unionIdx_spec`’s existential hypothesis at each step via (d)(4)(b)’s `mem_union_of_mem` applied to the running union (genuine, by the induction hypothesis) and the new atom (genuine, unconditionally, via `xPseqAtomIdx_mem`) plus `P1.surj`. `XFold_mem_iff` (the closed-form membership characterization, mirroring `yFold_mem_iff`) reuses `XFold_mem_of_found` at exactly the same step to legally rewrite through `unionIdx_spec` (replacing `unionUX`’s unconditional `UX_unionUX` rewrite).

`XPseqCode n := (XFold n (4n)).unpair.2`, `XPseqCode_mem/mem_XPseqCode_iff` specialize `XFold_mem_of_found/XFold_mem_iff` at $N = 4^n$, still conditional on `found`. **A flagged, deferred gap** (documented in-file, not faked): the *unconditional* form at $N = 4^n$ (mirroring `Theorem88d.lean`’s `exists_atomUEmpty_zero`) needs a genuine existence argument with no analogue here (`Theorem88d.lean`’s own proof is specific to its one-sided embedding structure) — investigation found a promising purely-algebraic covering route (`SplitSpec`’s unconditional $I \cup J = B$ plus the trivial $(A \cap X) \cup (A \setminus X) = A$, needing no case-adaptivity, showing the classical $\bigcup i < 4^n$, `(atomPairG ... n i).1` covers `D0.master`) but transporting it to the code level needs the *converse* half of `(d)(3)(d)`’s `atomPairCodeState_correct` (currently only “junk = 0 $\implies$ matches classical” is `Pass`; the reverse “classical non-empty $\implies$ junk = 0” is not yet proved) — substantial enough to warrant its own future sub-part. Lean gotchas hit and fixed: (1) a `(BIG_EXPR)\n.unpair.1` line-break inside a `have`’s type annotation parsed as *function application* of `.unpair/.1` as separate arguments rather than continued field projection (fix: keep the closing paren and `.unpair.1` glued with no line-break in between); (2) `include h in` must precede the *docstring*, not sit between the docstring and the `theorem` keyword (else “unexpected token ‘include’; expected ‘lemma’”) — same discipline as `(d)(3)(f)`’s `atomPairCodeState_disjoint` precedent, just easy to get backwards when writing fresh. Axiom-audited: `XPseqCode_mem/mem_XPseqCode_iff/primrec_XPseqCode` all depend on `[propext, Classical.choice Quot.sound]` (ambient baseline). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(c)(i): one-step 4-way classical reunion

- **Mathematical Target:** ranging over all four $(b_1, b_2) : \text{Bool} \times \text{Bool}$, the depth- $(n+1)$ `D0`-pieces of `atomPairG` reunion to *exactly* the depth- n parent’s `D0`-piece (`atomPairG_fst_union_step`)
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean`
- **Proof Notes:** Context for `(c)(i)–(c)(vi)`, done in response to a “reads as a fail?” concern about `(c)`’s flagged gap above: re-examination found it’s more tractable than the docstring suggested. Chasing the exact hypotheses already `Pass` elsewhere in `Exercise812d.lean` (`xStepG_spec`, `atomPairG_invariant`, `hxSplit : SplitSpec' D1 splitX, split_fst_subset'/split_snd_subset'`, and especially `emptyInterDec_eq_one_iff/emptyDiffDec_eq_one_iff` — which *already* give the full biconditional linking a decider’s reading to genuine classical set-emptiness, not just consistency) shows every one of `(c)(i)–(c)(vi)` has a concrete existing lemma to build on; nothing needs new axioms or hypotheses beyond the ambient baseline. **This sub-goal, done:** two new generic lemmas added to section `StepGen` (alongside `xStepG_fst_subset/yStepG_fst_subset`, matching their exact style): `xStepG_fst_union ((xStepG splitX A B Xn true).1  $\cup$  (xStepG splitX A B Xn false).1 = A`, the trivial `Set.inter_union_diff A Xn` identity restated through `xStepG`’s `.1`, no `SplitSpec'` hypotheses needed) and `yStepG_fst_union ((yStepG splitY A1 B1 Yn true).1  $\cup$  (yStepG splitY A1 B1 Yn false).1 = A1`, directly `hySplit`’s own `.2.2.2.2.1` field of `SplitSpec'`, given `hBA/hAmem` hypotheses). `atomPairG_fst_union_step` (in section `AtomPairGen`, placed just before `atomPairG_disjoint`) chains both at depth n : derives the two half-step invariant facts (`hBAtrue/hAmemtrue/hBAfalse` inline via the same case-split `xStepG_spec` itself uses (needed fresh since `xStepG_spec` is hardcoded to $(\delta n).1$ rather than a free `b1`), then two rows with `yStepG_fst_union` at each `b1` value reduce the goal to `xStepG_fst_union`. No Lean gotchas — went through on the first attempt, `simp only [xStepG, xyStep]/simp only [xStepG, xyStep, if_true]` handled the literal `true/false` substitutions cleanly (matching the file’s existing

if_true-driven idiom). **One open question, flagged but not re-litigated here:** IsComputableSplit's posIdx_spec/negIdx_spec are unconditional equalities to Q.X (posIdx ...) (always mem-genuine, by ComputablePresentation.mem_X's totality) for *every* n, m, k, which sits in apparent tension with the classical hxSplit/hySplit : SplitSpec' ... hypotheses (which allow genuinely- $\emptyset$ outputs) — the two are already used together successfully in (d)(1)/(d)(3)(f), so it hasn't blocked prior Pass work; this sub-goal and (c)(v) depend only on the classical SplitSpec' fields, never on posIdx_spec/negIdx_spec's unconditional-genuineness reading, staying on the side that's already load-bearing elsewhere. Axiom-audited: atomPairG_fst_union_step/xStepG_fst_union give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline, matching sibling lemmas xStepG_fst_subset/yStepG_fst_subset exactly); yStepG_fst_union gives the smaller $\subseteq \{\text{propext}\}$ (also matching yStepG_fst_subset). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(c)(ii): classical covering induction

- **Mathematical Target:** $\forall z \in D_0.\text{master}, \exists \delta' : \text{Fin } n \rightarrow \text{Bool} \times \text{Bool}, z \in (\text{atomPairG } (\text{extendTruePair } \delta') \ n).1$ — the classical pieces at depth n, ranged over all sign-histories, cover $D_0.\text{master}$
- **Lean File:** Scott1980/Neighborhood/Exercise812d.lean (atomPairG_master_covered)
- **Proof Notes:** induction on n chaining (c)(i)'s atomPairG_fst_union_step at every step; base case $n = 0$ trivial (atomPairG _ 0 = ($D_0.\text{master}$, $D_1.\text{master}$) definitionally, so $\langle \text{Fin.elim0}, \text{hz} \rangle$ closes it directly — $\text{Fin } 0$ has exactly one inhabitant of $\text{Fin } 0 \rightarrow \text{Bool} \times \text{Bool}$ anyway). Successor step: given a covering history $\delta'_0 : \text{Fin } n \rightarrow \text{Bool} \times \text{Bool}$ for z (from the IH), atomPairG_fst_union_step places z in one of the four (b1, b2) branches; extend δ'_0 by that bit using the project's standard Function.update-based device ($\delta'' := \text{Function.update } (\text{extendTruePair } \delta'_0) \ n \ (b1, b2)$), then restrictFinPair $\delta'' \ (n+1)$ to land back in $\text{Fin } (n+1) \rightarrow \text{Bool} \times \text{Bool}$ — this exactly mirrors Exercise812c.lean's xStep_spec_bit/yStep_fst_eq_inter_YPseq proofs, reusing atomPairG_congr (agreement below n via Function.update_of_ne, agreement below n+1 via extendTruePair_restrictFinPair_agree) and atomPairG_succ_eq. One small fix needed: Set.mem_union.mp isn't directly usable as a term (Set.mem_union isn't stated as a bare Iff without its Set.mem_union z s t application) — switched to simp only [Set.mem_union] at $h\delta'_0$ before the 4-way rcases. Stated as an existential rather than Set.iUnion — that's all (c)(iv) needs. Axiom-audited: $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline, matching atomPairG_fst_union_step). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(c)(iii): encode sign-histories as deltaPair-matching bit-sources

- **Mathematical Target:** a new definition encodeDeltaPair with $\forall i < n, \text{deltaPair } (\text{encodeDeltaPair } \delta \ n) \ i = \delta \ i$ — the base-4-digit inverse of (d)(3)(d)'s deltaPair
- **Lean File:** Scott1980/Neighborhood/Exercise812d.lean (encodeDeltaPair/encodeDeltaPair_lt/deltaPair_encodeDeltaPair/atomPairG_master_covered_deltaPair)
- **Proof Notes:** **Signature adjustment from the original scoping:** implemented encodeDeltaPair ($\delta : \mathbb{N} \rightarrow \text{Bool} \times \text{Bool}$) : $\mathbb{N} \rightarrow \mathbb{N}$ (a total δ , indexed by depth n as a second argument) rather than $(\text{Fin } n \rightarrow \text{Bool} \times \text{Bool}) \rightarrow \mathbb{N}$ — mirrors Theorem88d.lean's encodeBits ($\delta : \mathbb{N} \rightarrow \text{Bool}$) : $\mathbb{N} \rightarrow \mathbb{N}$ precedent exactly (same recursive-on-n shape, encodeBits $\delta \ n < 2^n / \text{deltaOf_encodeBits}$), reusing its proof strategy directly rather

than inventing a `Fin n`-indexed variant; at the call site (`atomPairG_master_covered_deltaPair` below) the `Fin n → Bool × Bool` history from (c)(ii) is simply padded via `extendTruePair` first. **Construction:** `encodeDeltaPair δ (n+1) := encodeDeltaPair δ n + digit * 4n` where `digit := (if (δ n).1 then 1 else 0) + (if (δ n).2 then 2 else 0) ∈ {0,1,2,3}` packs `(δ n).1/(δ n).2` into one base-4 digit's two bits, mirroring exactly how `atomPairStep` unpacks a digit `(rem % 2, (rem / 2) % 2)`. `encodeDeltaPair_lt (< 4n, mirroring encodeBits_lt)` is a one-line induction closed by `omega` given the digit's ≤ 3 bound (four-way `Bool` case split). **The inversion property** `deltaPair_encodeDeltaPair (∀ n i, i < n → deltaPair (encodeDeltaPair δ n) i = δ i`, mirroring `deltaOf_encodeBits`) needed genuinely new base-4 arithmetic (no `Nat.testBit`-style API to lean on, unlike `encodeBits`'s base-2 proof): two small private helpers, `digit_add_mul_pow_of_lt` (adding a higher digit `d * 4n`, `n > i`, never disturbs digit `i` — via `Nat.exists_eq_add_of_lt` to write `n = i+j+1`, ring to regroup `d * 4(i+j+1) = 4i * (4 * 4j * d)`, then `Nat.add_mul_div_left + Nat.add_mul_mod_self_left`) and `digit_eq_of_encodeDeltaPair` (the freshly-added digit at position `n` is read straight back off, since the lower part is $< 4^n$ by `encodeDeltaPair_lt` and so contributes 0 to the quotient, via `Nat.add_mul_div_right + Nat.div_eq_of_lt`). The main induction then splits `i < n ∨ i = n` (`Nat.lt_succ_iff_lt_or_eq`): the `i < n` case reduces both %2-bit-extractions to the digit-equality fact via `omega` (given `digit_add_mul_pow_of_lt`'s mod-4 equality, `omega` derives the two mod-2 facts for free) then closes via the IH; the `i = n` case reads off the fresh digit and closes by a four-way `Bool` case split (`Prod.ext_iff` to turn the resulting pair equality into two component equalities). **The covering-transport corollary** `atomPairG_master_covered_deltaPair` (new section `AtomPairGenDelta`, since `deltaPair` is declared textually after section `AtomPairGen` closes, so needed its own copy of the same `variable/include` block) chains (c)(ii)'s `atomPairG_master_covered` with `encodeDeltaPair/deltaPair_encodeDeltaPair` and `atomPairG_congr`, landing on exactly $\forall z \in D_0.\text{master}, \exists i < 4^n, z \in (\text{atomPairG}(\text{deltaPair } i) n).1$ as targeted. All prototyped first in a scratch file against a plain `import Mathlib` to save iteration cycles before integrating (per the arithmetic's novelty) — went in cleanly on the first attempt post-prototyping. Axiom-audited: all three depend on $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(c)(iv): non-trivial intersection with $P_0.X_n$, still classical

- **Mathematical Target:** $\exists i < 4^n, (\text{atomPairG}(\text{deltaPair } i) n).1 \cap P_0.X_n \neq \emptyset$
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (`exists_atomPairG_deltaPair_inter_Xn_ne_empty`, new section `AtomPairCorrect4`)
- **Proof Notes:** combines (c)(iii)'s `atomPairG_master_covered_deltaPair` with $P_0.X_n \subseteq D_0.\text{master} (D_0.\text{sub_master})$ and $P_0.X_n \neq \emptyset$: any $z \in P_0.X_n$ lands in some covering piece from (c)(iii), giving the non-trivial intersection at that piece's `i`. **One new hypothesis needed, flagged in-file:** $P_0.X_n \neq \emptyset$ needs `hD0nomin.mem_ne_empty (P0.mem_X n)` — genuine `NoMinimal` for D_0 , not just `IsPositive/DiffClosed/SplitSpec' /master.None` (d)(1)'s docstring explicitly says the generalized `atomPairG` layer “no longer needs `NoMinimal` anywhere”, and that remains true for the *construction*; but (c)(iv) is the one place in the whole closure that needs the *global* fact “every genuine neighbourhood (not just the master) is non-empty”, which only `NoMinimal` supplies (`master.Nonempty` alone is a strictly weaker, purely-local fact about one specific set). Added `hD0nomin : D0.NoMinimal` to a fresh section `AtomPairCorrect4` (mirroring `AtomPairCorrect3`'s variable list, since this needs both the (d)(1)-style abstract hypotheses *and* P_0/P_1 to talk about $P_0.X$

$n/\text{deltaPair}$), alongside the section’s own docstring update explaining why. No Lean gotchas — direct composition of already-Pass pieces. Axiom-audited: $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline). Whole-project lake build (3164 jobs) green, zero sorry. Also updated the file’s “flagged, deferred gap” docstring (just above `YPseqCode`’s section) to note the classical half of the promising route is now fully done $((c)(i)-(c)(iv))$, narrowing what’s left to $(c)(v)/(c)(vi)$ ’s converse-biconditional.

Exercise 8.12(d)(4)(c)(v): the converse-biconditional — (c)’s originally-named gap, now itself a concrete induction

- **Mathematical Target:** $(\text{atomPairG } (\text{deltaPair } i) \ n).1 \neq \emptyset \rightarrow \text{atomPairJunk } n \ i = 0$ ($\text{atomPairG_fst_eq_empty_of_junk_eq_one}$ for the contrapositive induction, then $\text{atomPairJunk_eq_zero_of_ne_empty}$ for the stated form)
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (new section `AtomPairCorrect5`, between `AtomPairCorrect4` and the “flagged, deferred gap” docstring)
- **Proof Notes:** proved as the contrapositive “junk newly 1 at some step $\implies$ the classical component is already $\emptyset$ from that step on forever”, by induction on n (base case $n = 0$ trivial: atomPairJunk is unconditionally 0 there, via `stateBase2`’s literal 0 junk field, so the hypothesis $= 1$ is vacuous). Successor step case-splits on $\text{atomPairJunk } n \ i$ (via `Nat.eq_zero_or_pos`): (**already junk at n**) propagate forward via $\text{atomPairG_fst_subset } ((d)(1), \text{already Pass})$ plus `Set.subset_eq_empty` and the induction hypothesis; (**freshly junk at $n+1$, i.e. $\text{atomPairJunk } n \ i = 0$**) first invoke $\text{atomPairCodeState_correct}$ ’s forward half $((d)(3)(d), \text{already Pass})$ to identify $P_0.X/P_1.X$ of the depth- n recorded indices with the classical $\text{atomPairG } n$ components exactly, then unfold $\text{atomPairJunk } (n+1) \ i$ one step ($\text{atomPairCodeState_succ}/\text{atomPairStep}/\text{xSubStep_junk_eq}/\text{ySubStep_junk_eq}$, the same unfolding chain $\text{atomPairCodeState_correct}$ ’s own proof uses) down to $\text{selectFn } x\text{check } 1 \ y\text{check} = 1$ where $x\text{check}/y\text{check}$ are the two half-steps’ direct-refine emptiness-decider readouts, and case-splits on $x\text{check}$ ’s value (bounded ≤ 1 via `selectFn_le_one + emptyInterDec_le_one/emptyDiffDec_le_one`): (**a**) $x\text{check} = 1$ — $\text{emptyInterDec_eq_one_iff}/\text{emptyDiffDec_eq_one_iff}$ (under `IsPositive/DiffClosed+NoMinima`) converts the decider readout directly into $(\text{atomPairG } n).1 \cap/\wedge P_0.X \ n = \emptyset$, i.e. $(x\text{StepG } \dots (\delta \ n).1).1 = \emptyset$ by definitional unfolding of $x\text{StepG}/xy\text{Step}$; then $x\text{StepG_spec } ((d)(1))$ supplies exactly the `SplitSpec`’-preconditions $y\text{StepG_fst_subset}$ needs to conclude $(\text{atomPairG } (n+1)).1 \subseteq (x\text{StepG } \dots).1 = \emptyset$ regardless of the Y-sub-step’s own bit — (**b**) $x\text{check} = 0$ — the X-sub-step is then genuinely non-junk (one more `selectFn\_zero` chase), so $x\text{SubStep_correct } ((d)(3)(d))$ ’s `AtomPairCorrect2`, already Pass, unconditional in A/B) identifies the X-sub-step’s own output indices with $x\text{StepG}$ ’s two components exactly; $h\text{junk1}$ then collapses (via `selectFn\_zero` again) to $y\text{check} = 1$ directly, and the same $\text{emptyInterDec_eq_one_iff}/\text{emptyDiffDec_eq_one_iff}$ machinery (now for P_1/D_1) gives $(\text{atomPairG } (n+1)).2 = \emptyset$ (the Y-sub-step’s *direct* refine is literally the D_1 -side, so no subset-propagation needed, only a definitional rewrite through $y\text{StepG}/xy\text{Step}/\text{Prod.swap}$); finally $\text{atomPairG_invariant}$ ’s $.1 = \emptyset \leftrightarrow .2 = \emptyset$ dichotomy *at depth $n+1$* transfers this to the targeted D_0 -side. $\text{atomPairJunk_eq_zero_of_ne_empty}$ (the exercise’s originally-named gap statement) is then the routine contrapositive, one by `contra+omega` (using $\text{atomPairJunk_le_one}$ to turn “ $\neq 0$ ” into “ $= 1$ ”) away from the induction. No Lean gotchas beyond one recurring pitfall: `rw [someIdxEq]` targeting a hypothesis of shape `emptyInterDec P (pair idx n) = 1` fails silently-looking (pattern not found) unless the `Nat`-level decider equation is first converted to the genuine `Set`-level equality via `_eq_one_iff` — only *then* does $P.X \ \text{idx}$ appear syntactically for `rw [hidxEq]` to fire (hit this twice, in both the (a)/(b) branches, before reordering fixed

it). Axiom-audited (`#print axioms`): both theorems $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this closure’s established baseline (inherited via `emptyInterDec_eq_zero_iff`’s `IsPositive/NoMinimal` case-splitting, not new here). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(c)(vi): assemble into the unconditional “found” fact

- **Mathematical Target:** $\exists i < 4^n$, `xPseqAtomJunk n i = 0`, unconditionally — then specialize into unconditional `XPseqCode_mem/mem_XPseqCode_iff` (dropping their `hfound` hypothesis)
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (new section `XPseqCodeUnconditional`, between `AtomPairCorrect5` and `YPseqCode`’s own section, replacing the old “flagged, deferred gap” docstring)
- **Proof Notes:** executed exactly as scoped, in four theorems chained straight through, no surprises. (1) `xPseqAtomJunk_exists_zero` (the mathematical heart): (c)(iv)’s `exists_atomPairG_deltaPair_inter_Xn_ne_empty` gives a bit-source $i < 4^n$ with $(\text{atomPairG} \dots n).1 \cap P_0.X \neq \emptyset$, hence (via `Set.subset_eq_empty Set.inter_subset_left`, contrapositive) $(\text{atomPairG} \dots n).1 \neq \emptyset$; (c)(v)’s `atomPairJunk_eq_zero_of_ne_empty` converts this to `atomPairJunk n i = 0`; (d)(3)(d)’s `atomPairCodeState_correct` (forward half, applicable now that the junk hypothesis is discharged) rewrites the classical piece as $P_0.X (\text{atomPairIdx0} \dots n i)$, transporting the non-trivial intersection to the code level; `emptyInterDec_eq_one_iff`’s converse (contrapositive via `emptyInterDec_le_one`, one by `contra+omega`) reads this off as `emptyInterDec P_0 (atomPairIdx0 ... n i, n) = 0`, which is exactly `xPseqAtomJunk_eq`’s value once `atomPairJunk n i = 0` collapses the outer `selectFn (selectFn_zero)`. (2) `XFold_four_pow_found`: transports (1) through `XFold_found_iff` at $N = 4^n$, mirroring `Theorem88d.lean`’s `yFold_two_pow_found` precedent exactly. (3)/(4) `XPseqCode_mem_unconditional/mem_XPseqCode_iff_unconditional`: re-specializations of the pre-existing conditional `XPseqCode_mem/mem_XPseqCode_iff` ((d)(4)(c)’s own construction row) at (2)’s unconditional witness — new names (not overwriting the conditional originals, since nothing else in the file depends on those being replaced, and both forms are informative) rather than reusing `XPseqCode_mem/mem_XPseqCode_iff` verbatim (Lean forbids re-declaring a closed name). Needed a new section (`XPseqCodeUnconditional`) rather than reusing the pre-existing `XPseqCode/AtomPairCorrect4/AtomPairCorrect5` sections, since the unconditional closure needs the *union* of hypotheses from all three ($P_0/P_1/\text{diff}/\text{split}$ computability for the code-level pieces, `hD0pos/hD0diff/hD0nomin/hxSplit/hD1pos/hD1diff/hD1nomin/hySplit/hD0mne/hD1` for the classical existence argument, `hUnion1` for the fold itself) — exactly `AtomPairCorrect5`’s variable list plus `hUnion1`. No Lean gotchas; verified signatures of all four upstream lemmas (`exists_atomPairG_deltaPair_inter_Xn_ne_empty`, `atomPairJunk_eq_zero_of_ne_empty`, `atomPairCodeState_correct`, `emptyInterDec_eq_one_iff`) via a scratch `#check` file before wiring the call sites, to get argument order exactly right on the first attempt. Axiom-audited (`#print axioms`): all four new theorems give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this closure’s established baseline throughout. Whole-project lake build (3164 jobs) green, zero sorry. (d)(4)(c) is now fully Pass, unconditionally, all of (c)(i)–(c)(vi).

Exercise 8.12(d)(4)(d)

- **Mathematical Target:** `YPseqCode`, the code-level Y-side union fold (double union), with closed-form correctness
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean`

- **Proof Notes:** symmetric to (c)’s `XPseqCode`, but `ySubStep`’s inputs already depend on position `n`’s own X-sub-step bit (per `Exercise812c.lean`’s own `YPseq` docstring), so the half-step atom needs an *extra* free bit `bx`: `yPseqAtomState n i bx` runs `xSubStep` at bit `bx` (arbitrary) then `ySubStep` at bit 1 (forced); `yPseqAtomIdx/yPseqAtomJunk` harvest `stateIdx0/stateJunk` (D_0 -side, since `ySubStep`’s “+” branch is the *split* side). Built as an **outer 2-way union of two inner 4^n -folds** (`YFoldInner n 0 _/YFoldInner n 1 _`, one per literal `bx`) rather than a single $2 \cdot 4^n$ -element fold — simpler than threading `bx` through the recursion state, since `Nat.Primrec.prec` already needs a fixed outer parameter and pairing `bx` alongside `n` costs nothing (`YFoldInnerPair`, a `z`-repackaged auxiliary, keeps `primrec_YFoldInner`’s own proof cheap: the `Nat.pair/unpair` round-trip needed to re-derive `n/bx` from a packed `z` is *not* `rfl` — it needs `pair_unpair`’s `Nat.sqrt` case split — so pushing it through `unpair_pair_fst/_snd`-driven `simp` instead of the kernel’s `whnf` avoids a heartbeat timeout hit on the first attempt). The two inner folds are then combined via a new, reusable `combineFound2` helper (generic in any `IsComputableUnion`): unions both codes when both found something, else propagates whichever single side found something. `YFoldInner`’s own correctness (`found_le_one/found_iff/mem_of_found/mem_iff`) exactly mirrors `XFold`’s four theorems verbatim (with `hD0pos/hD0diff/hD0nomin/hUnion0/D0/P0` in place of the D_1 versions, plus a held-fixed `bx` with `hbx : bx ≤ 1`); `combineFound2`’s own four correctness theorems are new (one level up: `found_le_one/found_iff` by direct case split on both sides’ found flags, `mem_of_found/mem_iff` reusing (d)(4)(b)’s `mem_union_of_mem` exactly as `XFold_mem_of_found` did). `YPseqCode n := (combineFound2 (YFoldInner n 0 (4^n)) (YFoldInner n 1 (4^n))).unpair.2`; `YPseqCode_mem/mem_YPseqCode_iff` specialize both layers together, conditional on the *combined* found flag (a genuine 4^n -atom on *either* `bx`-branch suffices). Same deferred gap as (c): unconditional found-ness is not proved (would need the same `converse-atomPairCodeState_correct` biconditional, doubled over `bx`).

Exercise 8.12(d)(4)(d)(i): one-step 4-way classical reunion, D_1 -side

- **Mathematical Target:** the depth- $(n+1)$ D_1 -pieces of `atomPairG` reunion to the depth- n parent’s D_1 -piece (`atomPairG_snd_union_step`)
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (`atomPairG_snd_union_step` in section `AtomPairGen`, placed immediately after `atomPairG_fst_union_step`; two new helper lemmas `yStepG_snd_union/xStepG_snd_union` in section `StepGen`, placed immediately after `yStepG_fst_union`)
- **Proof Notes:** mirror of (c)(i)’s two-fact chain, but with the roles of the “hypothesis-free trivial identity” and the “`SplitSpec`’-needing field extraction” lemma **swapped between the inner/outer collapse**, since D_1 ’s side (.2) is `yStep`’s own *direct-refine* side (trivial, no hypotheses) but `xStep`’s own *split* side (needs `hxSplit`) — exactly the reverse of D_0 ’s side (.1), which is `xStep`’s *direct-refine* side (trivial) but `yStep`’s *split* side (needs `hySplit`). Concretely: `yStepG_snd_union ((yStepG splitY A1 B1 Yn true).2 ∪ (yStepG splitY A1 B1 Yn false).2 = B1)` is the trivial `Set.inter_union_diff B1 Yn` identity through `yStepG`’s .2 (the *.swap*-ed *direct-refine* side) — no `SplitSpec`’ hypotheses needed, mirroring `xStepG_fst_union` exactly (just on the other step/side pairing). `xStepG_snd_union ((xStepG splitX A B Xn true).2 ∪ (xStepG splitX A B Xn false).2 = B)` reads off `SplitSpec`’s unconditional `I ∪ J = B` field directly (no *.swap*, unlike `yStepG_fst_union`’s use of the same field) — mirroring `yStepG_fst_union` exactly. `atomPairG_snd_union_step`’s proof is then genuinely *simpler* than `atomPairG_fst_union_step`’s: no per-branch *haves* (`hBAtrue/hAtrue/etc.`) are needed at all, because the *inner* (b_2 -level) collapse via `yStepG_snd_union` is hypothesis-free, so both

rws fire immediately off `atomPairG_invariant`'s bare `ihAB/ihA/ihB`, leaving only the outer `xStepG_snd_union hxSplit ihAB ihB (X n)` call to close the goal. No Lean gotchas. Axiom-audited (`#print axioms`): `yStepG_snd_union/atomPairG_snd_union_step` give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline, matching `xStepG_fst_union/atomPairG_fst_union_step`'s own footprint exactly); `xStepG_snd_union` gives the smaller $\subseteq \{\text{propext}\}$ (matching `yStepG_fst_union`'s own smaller footprint) — the same swapped-role pattern shows up in the axiom footprints too. Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(d)(ii): classical covering induction, D_1 -side

- **Mathematical Target:** $\forall z \in D_1.\text{master}, \exists \delta' : \text{Fin } n \rightarrow \text{Bool} \times \text{Bool}, z \in (\text{atomPairG } (\text{extendTruePair } \delta') \text{ } n).2 (\text{atomPairG_master_covered_snd})$
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (`atomPairG_master_covered_snd`, placed immediately after `atomPairG_master_covered` in section `AtomPairGen`)
- **Proof Notes:** a verbatim transcription of `atomPairG_master_covered`'s proof, swapping `.1`→`.2`, `D0.master`→`D1.master`, and `atomPairG_fst_union_step`→`atomPairG_snd_union_step` throughout — induction on `n`, base case trivial (`atomPairG _ 0 = (D0.master, D1.master)`, one piece covering itself), successor step extending a covering history $\delta'_0 : \text{Fin } n \rightarrow \text{Bool} \times \text{Bool}$ for `z` by one more `(b1, b2) : Bool × Bool` bit via the same `Function.update/restrictFinPair` device (`atomPairG_congr` for the agreement lemmas), picking whichever of the four `atomPairG_snd_union_step` branches `z` actually landed in via the same `(h1|h2)|(h3|h4)` 4-way `rcases`. No adaptation needed beyond the mechanical swap — (d)(i)'s `atomPairG_snd_union_step` has the identical $((b1=\text{true}, b2=\text{true}) \cup (b1=\text{true}, b2=\text{false})) \cup ((b1=\text{false}, b2=\text{true}) \cup (b1=\text{false}, b2=\text{false}))$ grouping as `atomPairG_fst_union_step`, so the same case split lines up exactly. No Lean gotchas. Axiom-audited (`#print axioms`): $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline, matching `atomPairG_master_covered`'s own footprint). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(d)(iii): encode sign-histories as `deltaPair`-matching bit-sources, D_1 -side

- **Mathematical Target:** transport (d)(ii) into $\forall z \in D_1.\text{master}, \exists i < 4^n, z \in (\text{atomPairG } (\text{deltaPair } i) \text{ } n).2$
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (`atomPairG_master_covered_deltaPair_snd`, placed immediately after `atomPairG_master_covered_deltaPair` in section `AtomPairGenDelta`)
- **Proof Notes:** exactly as scoped — a verbatim transcription of (c)(iii)'s `atomPairG_master_covered_deltaPair` proof, swapping `.1`→`.2`, `D0.master`→`D1.master`, and `atomPairG_master_covered`→(d)(ii)'s `atomPairG_master_covered_snd`. No new base-4 encoding needed: `encodeDeltaPair/deltaPair/deltaPair_encodeDeltaPair/atomPairG_congr` are already symmetric in `.1/.2`, reused as-is. section `AtomPairGenDelta`'s existing `variable/include` block already covers exactly what `atomPairG_master_covered_snd` needs, so no new section was required. No Lean gotchas — went in cleanly on the first attempt. Axiom-audited (`#print axioms`): $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline, matching `atomPairG_master_covered_deltaPair`'s own footprint exactly). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(d)(iv): non-trivial intersection with $P_1.X\ n$, still classical

- **Mathematical Target:** $\exists i < 4^n, (\text{atomPairG } (\text{deltaPair } i) \ n).2 \cap P_1.X\ n \neq \emptyset$
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (`exists_atomPairG_deltaPair_inter_Yn_ne_empty`, new section `AtomPairCorrect4Snd`, placed immediately after `AtomPairCorrect4`)
- **Proof Notes:** exactly as scoped — a verbatim `.1→.2, D0→D1, P0→P1` transcription of (c)(iv)’s `exists_atomPairG_deltaPair_inter_Xn_ne_empty` proof: picks $z \in P_1.X\ n$ (nonempty via a fresh `hD1nomin : D1.NoMinimal`, the D_1 -side analogue of (c)(iv)’s one genuinely new hypothesis — (d)(1)’s generalized `atomPairG` layer doesn’t carry `NoMinimal` on either side, only `SplitSpec' / IsPositive / DiffClosed`), transports it to `D1.master` via `D1.sub_master`, then lands it in a covering piece via (d)(iii)’s `atomPairG_master_covered_deltaPair_snd` — that piece’s `i` is the witness. New section `AtomPairCorrect4Snd` mirrors `AtomPairCorrect4`’s exact variable list, swapping `hD0nomin` for `hD1nomin` (a new section was needed since `AtomPairCorrect4` itself doesn’t carry `hD1nomin`). As noted in the target, this alone doesn’t fix the `bx` bit `YPseqCode`’s fold also needs — that’s resolved only in (d)(vi). No Lean gotchas — went in cleanly on the first attempt. Axiom-audited (`#print axioms`): $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline, matching `exists_atomPairG_deltaPair_inter_Xn_ne_empty`’s own footprint exactly). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(d)(v): the converse-biconditional, D_1 -side

- **Mathematical Target:** $(\text{atomPairG } (\text{deltaPair } i) \ n).2 \neq \emptyset \rightarrow \text{atomPairJunk } n\ i = 0$
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (`atomPairG_snd_eq_empty_of_junk_eq_one/atomPairJunk_eq_zero_of_snd_ne_empty`, appended to the end of section `AtomPairCorrect5`, immediately before `end AtomPairCorrect5`)
- **Proof Notes:** confirmed the scoping note’s prediction exactly — **not** a naive `.1↔.2` transcription of (c)(v)’s proof, since the two per-step sub-cases’ roles genuinely *swap*. Both proofs share the identical unfolding chain down to `hjunk1 : selectFn xcheck 1 ycheck = 1` (`xcheck` tied to P_0/A_1 , `ycheck` tied to P_1/B_2 — this per-step algebra doesn’t know which side is being targeted). The two branches then diverge from (c)(v)’s own case analysis: **`xcheck = 0`** (X-sub-step non-junk) — the Y-sub-step’s own direct-refine check trips the D_1 -side (B2) *directly* via `emptyInterDec_eq_one_iff/emptyDiffDec_eq_one_iff (P1)`, and since B2 is this branch’s target here (unlike (c)(v), whose target A2 needed `atomPairG_invariant`’s dichotomy to hop across from this same B2 trigger), **no invariant hop is needed at all** — the branch closes directly off `xSubStep_correct`’s `hxB1` identification. **`xcheck = 1`** (X-sub-step’s own check trips) — `hA1eq : A1 = ∅` is derived identically to (c)(v)’s own derivation (same `emptyInterDec_eq_one_iff/emptyDiffDec_eq_one_iff` chase via P_0), but the target B2 now needs a hop *from A1 to B1* via `xStepG_spec`’s own half-step biconditional `hspecAB` (a purely local one-step fact, not the depth-crossing `atomPairG_invariant`), then propagates via the *trivial* `yStepG_snd_subset` (no `SplitSpec'` hypotheses at all) in place of (c)(v)’s `SplitSpec'`-needing `yStepG_fst_subset`. **Net effect: this D_1 -side proof needs `atomPairG_invariant` in neither branch — genuinely simpler than (c)(v)’s own proof**, the opposite direction of asymmetry from (d)(i)’s union-step swap (there the D_1 -side proof was shorter because its *inner* collapse was hypothesis-free; here it’s shorter because it avoids the invariant-hop machinery entirely). The “already junk, propagate” branch is a direct swap (`atomPairG_fst`

`subset` $\rightarrow$ `atomPairG_snd_subset`, already `Pass`); base case identical (`atomPairJunk` unconditionally 0 at $n = 0$). `atomPairJunk_eq_zero_of_snd_ne_empty` is the routine contrapositive, identical in shape to `(c)(v)`'s own. No Lean gotchas — went in cleanly on the first attempt (verified the exact `xStepG/yStepG` unfolding semantics — which side is the “direct-refine” vs. “split” — against `atomPairG_succ_eq/xStepG_spec/yStepG_snd_subset`'s definitions before writing, to correctly identify which branch needed the hop). Axiom-audited (`#print axioms`): both $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline, matching `(c)(v)`'s own footprint exactly). Whole-project lake build (3164 jobs) green, zero sorry.

Exercise 8.12(d)(4)(d)(vi): assemble into the unconditional “found” fact, doubled over `bx`

- **Mathematical Target:** $\exists i < 4^n, \exists bx \leq 1, \text{yPseqAtomJunk } n \ i \ bx = 0$, unconditionally — then specialize into unconditional `YPseqCode_mem/mem_YPseqCode_iff`
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (new section `YPseqCodeUnconditional`, placed immediately after `end YPseqCode`)
- **Proof Notes:** the scoping note's prediction about *which* `bx` needs no advance determination was right, but the actual mechanism was more involved than a direct `(d)(iv)+(d)(v)` chain, because `yPseqAtomJunk n i bx`'s own genuine (non-junk) content is **not** `(atomPairG (deltaPair i) n).2` itself (that's `(d)(iv)`'s covering target) but rather the *depth- n -plus-half-step* split piece `(xStepG splitX A B (P0.X n) bx).2 (A/B := atomPairG (deltaPair i) n's two components)` — one more half-step deeper, matching how `yPseqAtomState` actually runs `xSubStep` (at the free bit `bx`) *before* `ySubStep`. Bridged via `(d)(i)`'s `xStepG_snd_union`: since `(xStepG ... true).2  $\cup$  (xStepG ... false).2 = B` (needs `atomPairG_invariant`'s dichotomy $A = \emptyset \leftrightarrow B = \emptyset$ /B's mem-or-empty at depth n , *not* `xStepG_spec` — that lemma's dichotomy is pinned to δ n 's own bit, not a free chosen `bx`), `(d)(iv)`'s $B \cap P_1.X \ n \neq \emptyset$ forces (via `Set.union_inter_distrib_right` + a `by_contra/push Not union-nonempty split`) *at least one* of the two split pieces to itself meet $P_1.X \ n$ non-trivially — no need to know which in advance, confirming the scoping note. A new private one-bit-generic helper `yPseqAtomJunk_eq_zero_of_bit` (section `YPseqCodeUnconditional`) does the actual `xSubStep/ySubStep` chase for a *chosen* `b` : `Bool`: given `atomPairJunk n i = 0` (from `(d)(v)`'s `atomPairJunk_eq_zero_of_snd_ne_empty`, applicable since $B \cap P_1.X \ n \neq \emptyset \implies B \neq \emptyset$), the direct-refine piece `(xStepG ... b).1  $\neq \emptyset$` (itself derived from the split piece's non-emptiness via the *same* `SplitSpec'`-level dichotomy `hxSplit ihAB ihB (P0.X n)` used inside `xStepG_snd_union`'s own proof — applied here directly, generalized to a free `b` rather than reusing the δ n -pinned `xStepG_spec`) and the split piece meeting $P_1.X \ n$, chases: $hne \rightarrow$ (via `atomPairCodeState_correct`'s forward identification + `emptyInterDec_eq_one_iff/emptyDiffDec_eq_one_iff`'s converse, P_0 -side) `xSubStep`'s own junk check = 0 $\rightarrow$ `xSubStep_correct` identifies its D_1 -side output index with the classical split piece $\rightarrow$ the same `emptyInterDec_eq_one_iff` converse (now P_1 -side) on `hinter` collapses `ySubStep`'s forced-“+” junk check to 0, landing `yPseqAtomJunk n i (if b then 1 else 0) = 0`. Used `set` (not raw inline terms) for the packed depth- n state `s0` and the post-`xSubStep` state `s1` throughout this helper — the fully-inlined term nesting (four levels: `ySubStep/xSubStep/Nat.pair/packState2`) is deep enough that hand-tracking closing-paren counts across multi-line `haves` is genuinely error-prone (hit and fixed two paren-count mismatches before switching to `set`). `yPseqAtomJunk_exists_zero` then chains: `(d)(iv)` for $B \cap P_1.X \ n \neq \emptyset \rightarrow$ the `xStepG_snd_union` split above $\rightarrow$ the `SplitSpec'` dichotomy (`hspec1.2.2.1/hspec1.2.2.2.1`, picked via `mt ... .mp` contrapositives) $\rightarrow$ `yPseqAtomJunk_eq_zero_of_bit` on whichever

branch fired. `YFoldInner_or_found/YPseqCode_four_pow_found/YPseqCode_mem_unconditional/mem_YPseqCode_iff_unconditional` then mirror (c)(vi)’s own `XFold_four_pow_found/XPseqCode_mem_unconditional/mem_XPseqCode_iff_unconditional` chain exactly, with `YFoldInner_or_found` (new, doubled over `bx` via `interval_cases`) taking the place of a direct `XFold_found_iff` transport, and `combineFound2_found_iff` gluing the two `bx`-branches’ found flags together before specializing `YPseqCode_mem/mem_YPseqCode_iff`. Two Lean gotchas beyond the paren-counting one: (1) `exists_atomPairG_deltaPair_inter_Yn_ne_empty`’s actual signature (section `AtomPairCorrect4Snd`) does *not* carry `hDiff0/hDiff1/hSplitX/hSplitY` as parameters (unlike most theorems in this file) since its statement and proof never reference them — calling it with the “usual” full parameter list fails; (2) the included-but-unused-variable linter fires on the new private helper (it only needs 5 of the section’s 10 D-level hypotheses) — trimmed the `include` line down to exactly `hD0pos hD0diff hD0nomin hD1pos hD1nomin` (and updated both call sites) to silence it cleanly, rather than leaving the lint warning. Axiom-audited (`#print axioms`): all five new theorems $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (ambient baseline, matching (c)(vi)’s own footprint exactly). Whole-project lake build (3164 jobs) green, zero sorry. (d)(4)(d) is now fully Pass, unconditionally, all of (d)(i)–(d)(vi) — and per the (d)(4) umbrella, all of 8.12(d)(4)’s sub-parts (a)–(d) are now Pass.

Exercise 8.12(d)(5)

- **Mathematical Target:** `toD1/toD0`’s underlying maps are `IsComputableMap P0 P1/IsComputableMap P1 P0`
- **Lean File:** — (not yet started; re-scoped 2026-07-05, stopping before executing, per this project’s discipline)
- **Proof Notes:** Re-scoping investigation, done before writing any code, comparing against `Exercise812c.lean`’s actual `toD1/toD0/domainIso812c` construction (§`Iso`, ~330 lines) and `Theorem88n.lean`’s `isoInj/isoProj/ofIso` precedent:
 1. **Correction to the (d)(4)/(d)(6) cross-reference notes below (flagged 2026-07-04, found wrong on inspection 2026-07-05):** `domainIso812c` cannot be reused as-is. Those notes proposed `toMap := ofIso domainIso812c`, betting that `(ofIso domainIso812c).rel`’s unfolding would land on `XPseqCode/YPseqCode`. It does not: `domainIso812c`’s `toD1/toD0` are defined via `XPseq/YPseq` (`Exercise812c.lean`), which are hardcoded (through `atomPair`) to the *classical, choice-derived* `split splitChoice' D1 hD1nomin/splitChoice' D0 hD0nomin` — a **specific, non-constructive** witness of `NoMinimal`’s splitting existential, fixed once `hD0nomin/hD1nomin` are given, with **no reason to coincide** with whatever effectively-computable `splitX/splitY` (satisfying `SplitSpec'`) this sub-part is handed. `SplitSpec'` does not pin down a *unique* split of a given set — different valid splits generally carve out different disjoint nonempty pieces — so `atomPairG`’s (hence `XPseqCode`’s/`YPseqCode`’s) recovered neighbourhoods are, in general, literally different sets from `XPseq`’s/`YPseq`’s. Reusing `domainIso812c` would leave `(ofIso domainIso812c).rel (P0.X n) (P1.X m)`’s unfolding stuck on $\exists k, P_1.X m = XPseq D_0 D_1 hD_0nomin hD_1nomin P_0.X P_1.X k \wedge P_0.X n \subseteq P_0.X k$ — a condition about `splitChoice'`’s *classical* recovered sets, with no bridge to the *effective* `splitX/splitY/XPseqCode/YPseqCode` apparatus this whole (d) track exists to build. (d)(4)’s and (d)(6)’s rows have been annotated with a pointer to this correction.
 2. **The right fix:** a fresh, generalized order-iso, built directly on `atomPairG/XPseqCode/YPseqCode` mirroring `Exercise812c.lean`’s *entire* §`AtomPair`(vi)(5)(b)–(6) interleaving layer *and* §`Iso` assembly (c)(vii), generalized over `splitX/splitY`. Unlike

- (d) (4) (c) / (d) (4) (d) 's code-level folds — which bypassed that classical interleaving machinery entirely (per (d) (4) 's own finding 3: `XPseq_mem`'s heavy `combinedX/combinedY/transfer_inter_empty_combined` detour is unneeded for bare genuineness) — this sub-part's *cross-family order comparisons* (`up_mem`'s core content) have no such shortcut found yet: they inherently compare an arbitrary raw index $P_0.X\ i$ against a recovered union $P_1.X\ (YPseqCode\ j)$'s “other side”, which is exactly what `Exercise812c.lean`'s `combinedX/combinedY/combined $\delta$ /genAtom-interleaving/transfer_subset_combined/transfer_inter_eq_combined` machinery (~300 lines, (c)(vi)(5)(b)–(vi)(6)) was built to handle. **Grep-confirmed:** `Exercise812d.lean` currently has *zero* generalized analogues of any of this (`combinedXG/genAtomG/transfer_*G` all absent) — it is unstarted, not merely deferred.
3. **A genuine simplification specific to (d) (not available to (c)(vii)'s bare-enumeration setting):** `inter_mem/exists_inter_index_X/exists_inter_index_Y` need no interleaving detour at all. (c)(vii)'s `toD1/toD0` needed `exists_inter_index_X/Y` (via `hXcover/hYcover` plus the transfer layer) *only* because their `X/Y` parameters are bare index-enumeration functions with no built-in intersection primitive. Here, P_0/P_1 are full `ComputablePresentations` (Definition 7.1): $P_0.inter/P_1.inter$ (with `inter_spec`, `inter_primrec`) already hand back a primitive-recursive intersection index directly. So the generalized `toD1Code/toD0Code`'s `inter_mem` field can cite $P_1.inter\ i\ j/inter_spec$ directly, with **no classical existence detour and no `hXcover/hYcover` hypotheses needed for this field at all** — a genuine scope reduction versus (c)(vii)'s own proof, not just a mechanical transcription.
 4. **The zero/master facts likely need no interleaving either.** (c)(vi)(2)'s `XPseq_zero/YPseq_zero` are proved directly from `atomPair`'s own $n = 0$ unfolding plus `SplitSpec'` (not via `combinedX/genAtom`) — the generalized `atomPairG/XPseqCode/YPseqCode` analogues should transcribe the same direct argument, expected light.
 5. **The exercise's actual literal target, once the order-iso exists, is a clean `Theorem88n.lean`-style computability proof — genuinely new content, not yet attempted.** With a generalized `domainIsoCode812d : DomainIso D0 D1` in hand (built from `toD1Code/toD0Code`), of `Iso domainIsoCode812d`'s relation unfolds (via `toD1Code`'s definition and `V.principal`, mirroring `isoInj_rel_iff_incl`) to $\exists k, P_1.X\ m = P_1.X\ (XPseqCode\ k) \wedge P_0.X\ n \subseteq P_0.X\ k$ — now genuinely checkable: $P_1.X\ m = P_1.X\ (XPseqCode\ k)$ is `P1.eq_computable` (Definition 7.1, generic on any `ComputablePresentation`) reindexed by the already-`Nat.Primrec XPseqCode (primrec_XPseqCode, (d) (4) (c))`, conjoined with `P0.incl_computable`; the outer $\exists k$ over a decidable body is `REPred.of_iff-r.e.`, exactly `isoInj_isComputableMap`'s pattern. Symmetric for the $D_1 \rightarrow D_0$ direction via `YPseqCode`.
- **Design decision needed before executing (flagged, not resolved, pending user input):** should (d) (5) 's cross-family order facts (finding 2) be built by a **full, careful generalization** of `Exercise812c.lean`'s `combinedX/combinedY/genAtom-interleaving/transfer_*` chain (the *safe*, guaranteed-to-work route, directly mirroring ~300 lines of already-correct precedent line-for-line with `splitChoice' → splitX/splitY` and `atomPair → atomPairG` substitutions), or should the first executing session **first spend a bounded effort searching for a shortcut** directly from already-proven `atomPairG`-level facts (`atomPairG_disjoint`, `atomPairG_invariant`, `xStepG_snd_union`, (d) (4) (c) / (d) (4) (d) 's `mem_XPseqCode_iff_unconditional/mem_YPseqCode_iff_unconditional`) that might avoid rebuilding the interleaving layer wholesale? **The bounded-search-then-fallback route is recommended:** this project's own history ((d) (4) (b) 's `XPseqG/YPseqG` “unnecessary and not the right shape” finding) shows the heavy classical detours from (c) are sometimes avoidable once code-level closed forms are already in hand, so a short investigation is cheap

insurance before committing to the larger transcription — but the full-transcription route remains the fallback of known, bounded size if no shortcut turns up.

- **Sub-part breakdown:** re-scoped into 6 dependent sub-goals, (d)(5)(a)–(f) below, each its own block ((a) $\rightarrow$ (b) $\rightarrow$ (c) $\rightarrow$ (d) $\rightarrow$ (e) $\rightarrow$ (f)), strictly sequential — every later block’s target hypothesis-list is a strict superset of the ones before it, exactly as (d)(4)(c)’s (c)(i)–(vi) chain was).

Exercise 8.12(d)(5)(a): zero/master facts for XPseqCode/YPseqCode

- **Mathematical Target:** generalizing XPseq_zero/YPseq_zero ((c)(vi)(2)) to the code level. Needs two new hypotheses mirroring (c)(vii)’s own hX0/hY0 zero-convention (atomPairG’s recursion probes the *raw* index *n* at depth *n*, so depth-0’s probe is literally $P_0.X\ 0/P_1.X\ 0$, not $P_0.masterIdx/P_1.masterIdx$ — these do not coincide in general, so the convention must be assumed, exactly as (c)(vii) assumed it for bare X/Y):

- $hX0 : P_0.X\ 0 = D_0.master$, $hY0 : P_1.X\ 0 = D_1.master$ (new section hypotheses, threaded through every later sub-part).
- theorem XPseqCode_zero : $P_1.X\ (XPseqCode\ P_0\ P_1\ hDiff0\ hDiff1\ splitX\ hSplitX\ splitY\ hSplitY\ hUnion1\ 0) = D_1.master$
- theorem YPseqCode_zero : $P_0.X\ (YPseqCode\ P_0\ P_1\ hDiff0\ hDiff1\ splitX\ hSplitX\ splitY\ hSplitY\ hUnion0\ 0) = D_0.master$

- **Lean File:** Exercise812d.lean (new section XYPseqCodeZero, appended)
- **Proof Notes:** direct transcription of XPseq_zero/YPseq_zero’s proof strategy confirmed to work unmodified at the code level, plus two genuine simplifications found during execution that avoided finding 4’s interleaving layer entirely (as predicted) and *also* avoided any Fin *n*/deltaPair case-analysis on *i*:

1. **New generic helper atomPairJunk_zero (k) : atomPairJunk ... 0 k = 0** (atomPairCodeState base clause stateBase2 hardcodes junk 0 regardless of bit-source *k*; proved by unfold atomPairJunk; simp [atomPairCodeState, atomPairBase, stateBase2]), feeding atomPairCodeState_correct ... 0 0 (atomPairJunk_zero ...) unconditionally to get $P_0.X\ (atomPairIdx0\ \dots\ 0\ 0) = D_0.master/P_1.X\ (atomPairIdx1\ \dots\ 0\ 0) = D_1.master$ (atomPairG’s own *n* = 0 clause is defeq ($D_0.master, D_1.master$), so hcs.1/hcs.2 typecheck directly against those ascribed types with no further unfolding needed).
2. **xPseqAtomJunk ... 0 0 = 0 and $P_1.X\ (xPseqAtomIdx\ \dots\ 0\ 0) = D_1.master$** exactly by XPseq_zero’s own SplitSpec’ argument, transcribed line-for-line: hxSplit applied at $A = D_0.master, B = D_1.master, Xn = D_0.master$ (using hX0 to identify Xn with $P_0.X\ 0$) gives the “–”-branch = $\emptyset$ (Set.diff_self on $D_0.master \setminus D_0.master$) forcing the “+”-branch/posIdx — via IsComputableSplit.posIdx_spec — to the full union $D_1.master$; the junk-freeness itself falls out of emptyInterDec_eq_one_iff’s contrapositive ($D_0.master \cap D_0.master = D_0.master \neq \emptyset$ by hDomne).
3. **New generic helper xPseqAtomIdx0_eq** (the stateIdx0/direct-refine twin of the pre-existing xPseqAtomIdx_eq, same proof shape via xSubStep_idx0_eq instead of xSubStep_idx1_eq) plus ComputablePresentation.inter_spec (witness $k := atomPairIdx0\ \dots\ 0\ 0$ itself, since $P_0.X\ k \subseteq P_0.X\ k \cap P_0.X\ 0$ is an equality once both sides read $D_0.master$) gives the companion fact $P_0.X\ (stateIdx0\ (xPseqAtomState\ \dots\ 0\ 0)) = D_0.master$ — the “B”-input Y-side’s own split needs.

4. **Key shortcut (avoids rebuilding ySubStep/xSubStep unfolding machinery for the Y-side from scratch):** yPseqAtomState's inner xSubStep call at bit $bx = 1$ is *definitionally* xPseqAtomState (Nat.pair n (Nat.pair 1 (packState2 (atomPairIdx0 n i) (atomPairIdx1 n i) (atomPairJunk n i)))) is literally the same term whether the 1 comes from xPseqAtomState's hardcoded bit or yPseqAtomState's bx substituted with 1) — so stateJunk/stateIdx1 of that inner call are rfl-equal to xPseqAtomJunk/xPseqAtomIdx ... 0 0, letting ySubStep_junk_eq/ySubStep_idx0_eq at $bx = 1$ reuse finding 2/3's already-established facts directly (via show/type-ascription defeq, exactly xPseqAtomIdx_eq's own have h' : ... := h technique) rather than re-deriving them. The same SplitSpec' argument (hySplit at A = D₁.master, B = D₀.master, Xn = D₁.master) then gives yPseqAtomJunk ... 0 0 1 = 0 and P₀.X (yPseqAtomIdx ... 0 0 1) = D₀.master.
5. **The $\subseteq$ D₁.master/ $\subseteq$ D₀.master half of each equality needs no witness/case-analysis on i at all** (a further simplification over the original plan's “unique bit-source i = 0” framing): every half-step atom is mem-genuine *unconditionally*, regardless of junk status or bit-source (xPseqAtomIdx_mem/yPseqAtomIdx_mem, both pre-existing), so D₁.sub_master/D₀.sub_master closes that direction immediately from mem_XPseqCode_iff_unconditional/mem_YPseqCode_iff_unconditional's raw existential with no need to pin i = 0 — only the *reverse* ($\supseteq$) direction needs the explicit i = 0 witness with $0 < 4^0$. Both headline theorems assembled via Set.Subset.antisymm. Zero sorry; lake build (3165 jobs) and lake env lean Exercise812d.lean both clean (no new warnings, no unused-variable/unused-include lint hits). #print axioms on both gives $\subseteq$ {propext, Classical.choice, Quot.sound}, matching this section's established baseline (e.g. mem_XPseqCode_iff_unconditional, atomPairCodeState_correct carry the identical footprint) — no new choice introduced.

Exercise 8.12(d)(5)(b): the interleaving/order layer, generalized

- **Mathematical Target:** the same-family order/intersection transfer facts consumed by (d)(5)(c)/(d)(5)(d), generalizing X_subset_iff_XPseq_subset/YPseq_subset_iff_Y_subset/X_inter_eq_iff_XPseq_inter_eq/YPseq_inter_eq_iff_Y_inter_eq ((c)(vi)(6)):
 - theorem X_subset_iff_XPseqCode_subset (i j : ℕ) : P₀.X i $\subseteq$ P₀.X j $\leftrightarrow$ P₁.X (XPseqCode ... i) $\subseteq$ P₁.X (XPseqCode ... j)
 - theorem YPseqCode_subset_iff_Y_subset (i j : ℕ) : P₀.X (YPseqCode ... i) $\subseteq$ P₀.X (YPseqCode ... j) $\leftrightarrow$ P₁.X i $\subseteq$ P₁.X j
 - theorem X_inter_eq_iff_XPseqCode_inter_eq (i j k : ℕ) : P₀.X i $\cap$ P₀.X j = P₀.X k $\leftrightarrow$ P₁.X (XPseqCode ... i) $\cap$ P₁.X (XPseqCode ... j) = P₁.X (XPseqCode ... k)
 - theorem YPseqCode_inter_eq_iff_Y_inter_eq (i j k : ℕ) : P₀.X (YPseqCode ... i) $\cap$ P₀.X (YPseqCode ... j) = P₀.X (YPseqCode ... k) $\leftrightarrow$ P₁.X i $\cap$ P₁.X j = P₁.X k
- **Lean File:** Exercise812d.lean ((b)(i) done; (b)(ii)–(b)(iv) not yet started)
- **Design decision (RESOLVED 2026-07-05, after the bounded-search investigation the (d)(5) row asked for):** Route 1 is necessary — X_subset_iff_XPseqCode_subset etc. compare P₀.X i/P₀.X j, raw mutually-unrelated enumeration indices that are never themselves outputs of any atomPairG recursion (they are only ever *fed into* it as the Xn/Yn step argument), so there is no way to transport a subset/inter fact between two arbitrary such indices through atomPairG_disjoint/atomPairG_invariant/xStepG_snd_

union alone: those facts are all *single-depth* invariants of one fixed recursion run, not a same-family relation between two different indices. Route 2’s candidate shortcut does not exist; the full `combinedX/combinedY/genAtom`-interleaving apparatus (generalized) is needed, exactly as the (d)(5) row’s finding 2 anticipated. **However, a genuine, non-trivial simplification survives:** `Exercise812c.lean`’s own `xStep_snd_eq_inter_XPseq/yStep_fst_eq_inter_YPseq` “I-formula” lemmas (~270 lines, needed to seed the interleaved family’s odd-depth half-steps) are hard classically only because `XPseq/YPseq` union over the *uncountable* $\delta' : \mathbb{N} \rightarrow \text{Bool} \times \text{Bool}$; at the code level `XPseqCode/YPseqCode` union over *at most* 4^n *literally distinct* bit-sources, and any two distinct bit-sources both $< 4^n$ are *automatically* distinguished somewhere below n (new lemma `exists_deltaPair_ne_of_lt_of_ne`, via `Nat.eq_of_testBit_eq` reading `deltaPair` as two `testBits` per depth) — so the classical proof’s entire “does δ' agree with δ through n ?” case split never arises, collapsing ~60 lines of case analysis per I-formula to a single disjointness appeal (`atomPairCodeState_disjoint`). Re-scoped into 4 further sub-goals, (b)(i)–(b)(iv), strictly sequential.

Exercise 8.12(d)(5)(b)(i): the X-side I-formula for `XPseqCode`

- **Mathematical Target:** the code-level, bounded-existential analogue of `Exercise812c.lean`’s `xStep_snd_eq_inter_XPseq`, needed to seed (b)(iii)’s `combinedYCode`’s odd-depth half-step:

```
– theorem xPseqAtomIdx_eq_inter_XPseqCode {n k} (hk : k < 4 ^ n) (hjunk :
  xPseqAtomJunk ... n k = 0) : P1.X (xPseqAtomIdx ... n k) = P1.X (atomPairIdx1
  ... n k) ∩ P1.X (XPseqCode ... n)
```

- **Lean File:** `Exercise812d.lean` (new section `XPseqCodeIFormula`, appended)
- **Proof Notes:** three new lemmas, all reusable beyond this sub-part:
 1. `deltaPair_fst_eq_testBit/deltaPair_snd_eq_testBit`: `deltaPair k i = (k.testBit (2*i), k.testBit (2*i+1))` — `deltaPair` is `Nat.testBit` in disguise, two bits per depth (the base-4 analogue of `Theorem88d.lean`’s `deltaOf_eq_testBit`), via `Nat.testBit_eq_decide_div_mod_eq` and $4^i = 2^{(2 * i)}$.
 2. `eq_of_deltaPair_agree_of_lt_four_pow/exists_deltaPair_ne_of_lt_of_ne`: two bit-sources both $< 4^n$ agreeing (via `deltaPair`) on all of $[0, n)$ are equal — direct transcription of `Theorem88d.lean`’s `eq_of_deltaOf_agree_of_lt_two_pow`’s *strategy* (`Nat.eq_of_testBit_eq` + `Nat.testBit_lt_two_pow` on the bound), re-proving every bit $< 2 * n$ via finding 1’s two `testBit` readings per depth $< n$. Contrapositive form is what call sites actually use.
 3. `xPseqAtomIdx_subset_atomPairIdx1` (the $\subseteq$ -half, factored out for reuse at both bit-sources in the $\supseteq$ direction below): `hSplitX.posIdx`’s value is always $\subseteq$ its own D_1 -side companion `atomPairIdx1`, via `hSplitX.posIdx_spec` + `atomPairG_invariant` (to satisfy `hSplitX`’s hypotheses) + `SplitSpec`’s $\cup = B$ field (`Set.subset_union_left` composed with the union equation via `calc`, not `rw`, since naively `rw`-ing the union equation backwards over-substitutes the B that also appears as `splitX`’s own second argument).
 4. **The headline `xPseqAtomIdx_eq_inter_XPseqCode`:** $\subseteq$ is finding 3 plus membership in `XPseqCode n` via the *same* witness k ; $\supseteq$ takes `mem_XPseqCode_iff_unconditional`’s existential witness k' , case-splits $k' = k$ (trivial) vs $k' \neq k$ (impossible: finding 2 forces a `deltaPair`-disagreement below n , `atomPairCodeState_disjoint` then gives $P_1.X (\text{atomPairIdx1} \dots n k) \cap P_1.X (\text{atomPairIdx1} \dots$

$n \ k') = \emptyset$, contradicting z being in both via finding 3 applied at k'). No δ' -agreement case split anywhere, confirming the design-decision note’s predicted simplification. Two declarations needed `set_option maxHeartbeats 800000` (nested `atomPairG/ComputablePresentation` applications are large); one real bug caught along the way: `atomPairCodeState_correct`’s explicit arguments are $(k \ n : \mathbb{N})$ (bit-source *first*), not $(n \ k)$ — passing them in the wrong order caused a defeq-unification timeout rather than a type error, since both bind at type $\mathbb{N}$. Zero sorry; lake build (3165 jobs) clean, lake env lean Exercise812d.lean zero warnings. #print axioms on all three new theorems gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s baseline.

Exercise 8.12(d)(5)(b)(ii): the Y-side I-formula for YPseqCode

- **Mathematical Target:** the code-level analogue of Exercise812c.lean’s `yStep_fst_eq_inter_YPseq/yStep_fst_succ_eq`, needed to seed (b)(iii)’s combinedXCode’s odd-depth half-step:

```

- theorem yPseqAtomIdx_eq_inter_YPseqCode {n i} (hi : i < 4 ^ n) (b : Bool)
  (hjunk : yPseqAtomJunk ... n i (if b then 1 else 0) = 0) : P0.X (yPseqAtomIdx
    ... n i (if b then 1 else 0)) = (xStepG splitX (atomPairG ... (deltaPair
    i) n).1 (atomPairG ... (deltaPair i) n).2 (P0.X n) b).1 ∩ P0.X (YPseqCode
    ... n)

```

- **Lean File:** Exercise812d.lean (new section YPseqCodeIFormula, appended)
- **Proof Notes:** four new lemmas, structured as a chain of set-inclusions/disjointness facts feeding the headline, rather than a $bx = 0/bx = 1$ closed-form split (the originally anticipated approach) — it turned out unnecessary to reprove a $bx = 0$ analogue of `xPseqAtomIdx0_eq`, since the argument goes through uniformly for both bits of b via the *classical* `xStepG`-level set $((xStepG \text{ splitX } A \ B \ (P_0.X \ n) \ b).1)$ as the intermediate comparison target, sidestepping code-level case analysis on b entirely:

1. `atomPairJunk_eq_zero_of_yPseqAtomJunk`: a zero `yPseqAtomJunk n i (if b then 1 else 0)` propagates back to `atomPairJunk n i = 0` (peeling both the outer `ySubStep` and inner `xSubStep` junk-propagation layers via `ySubStep_junk_eq/xSubStep_junk_eq/junk_eq_zero_of_selectFn_eq_zero`).
2. `yPseqAtomIdx_subset_xStepGFst`: for non-junk (n, i, b) , $P_0.X \ (yPseqAtomIdx \dots n \ i \ (if \ b \ \text{then} \ 1 \ \text{else} \ 0)) \subseteq (xStepG \text{ splitX } A \ B \ (P_0.X \ n) \ b).1$ where $A, B := \text{atomPairG} \dots (\text{deltaPair } i) \ n$ — chases `xSubStep_correct/ySubStep_correct` through the packed state to identify `yPseqAtomIdx`’s value with $(yStepG \text{ splitY } (xStepG \dots b).1 \ (xStepG \dots b).2 \ (P_1.X \ n) \ \text{true}).1$, then applies `yStepG_fst_subset`.
3. `yPseqAtomIdx_subset_atomPairIdx0`: composes finding 2 with `xStepG_fst_subset` and `atomPairCodeState_correct` to get the coarser $P_0.X \ (yPseqAtomIdx \dots n \ i \ (if \ b \ \text{then} \ 1 \ \text{else} \ 0)) \subseteq P_0.X \ (\text{atomPairIdx0} \dots n \ i)$ — the bound needed to reach `atomPairCodeState_disjoint` in the “different i ” case below.
4. `yPseqAtomIdx_eq_of_dichotomy`: the two-source disjointness dichotomy for the $\supseteq$ direction — given z in the classical $(xStepG \dots b).1$ piece at target (i, b) and in `yPseqAtomIdx`’s witness `atom` at (i', b') , either $(i', b') = (i, b)$ (trivial) or contradiction: $i' \neq i$ uses $(b)(i)$ ’s `exists_deltaPair_ne_of_lt_of_ne` + `atomPairCodeState_disjoint` (finding 3 transports z up to the `atomPairIdx0`

level); $i' = i \wedge b' \neq b$ uses `xStepG_disjoint_of_ne` directly (finding 2 transports z up to the `xStepG`-level), confirming both disjointness sources are needed but showing the $i' = i$ one is the “cheap” `xStepG_disjoint_of_ne` appeal, not a raw-set $A \cap X_n/A \setminus X_n$ argument as originally guessed.

5. **The headline `yPseqAtomIdx_eq_inter_YPseqCode`:** $\subseteq$ is finding 2 plus `mem_YPseqCode_iff_unconditional`’s `Or.inl/Or.inr` membership via the same witness (i, b) ; $\supseteq$ takes `mem_YPseqCode_iff_unconditional`’s existential witness (i', b') from either disjunct) and applies finding 4. Zero sorry; lake build (2990 jobs) and lake env lean `Exercise812d.lean` both clean (one harmless `linter.unusedSectionVars` warning on two section variables unused in the dichotomy lemma, left as-is since trimming the shared `include/argument` list would silently reorder positional arguments at other call sites). `#print axioms yPseqAtomIdx_eq_inter_YPseqCode` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, identical to (b)(i)’s headline footprint.

Exercise 8.12(d)(5)(b)(iii): `combinedXCode/combinedYCode/combined $\delta$` , and `hcore`

- **Mathematical Target:** the generalized interleaved-family machinery, mirroring `Exercise812c.lean`’s `combinedX/combinedY/combined $\delta$` (lines 1236–1457) with `atomPair  $\rightarrow$  atomPairG, splitChoice'  $\rightarrow$  splitX/splitY, XPseq  $k \rightarrow P_1.X$  (XPseqCode ...  $k$ ), YPseq  $k \rightarrow P_0.X$  (YPseqCode ...  $k$ ):`
- `combinedXCode(2k) := P0.X k, combinedXCode(2k+1) := P0.X (YPseqCode ... k); combinedYCode(2k) := P1.X (XPseqCode ... k), combinedYCode(2k+1) := P1.X k; combined $\delta$ /deinterleave $\delta$` reused verbatim from `Exercise812c.lean` (pure functions of $\mathbb{N} \rightarrow \text{Bool} \times \text{Bool}/\mathbb{N} \rightarrow \text{Bool}$ and $\mathbb{N}$, no $X/Y/D_0/D_1$ dependence).
- Odd-depth half-step identities `genAtom_combinedXCode_succ_eq/genAtom_combinedYCode_succ_eq`.
- `atomPairG_fst_eq_genAtomCode/atomPairG_snd_eq_genAtomCode` (induction on n).
- `hcoreCode_even/hcoreCode_odd/hcoreCode` (via `deinterleave $\delta$ /combined $\delta$ _deinterleave $\delta$ , atomPairG_invariant`’s clause (a), and `xStepG_spec`’s matching-emptiness clause — both already Pass, no new content).
- **Lean File:** `Exercise812d.lean` (new section `CombinedCode`, appended)
- **Proof Notes:** the two genuinely new “two-branch closed form” lemmas, generalizing (b)(i)/(b)(ii)’s bounded-bit-source I-formulas up to an *arbitrary* $\delta : \mathbb{N} \rightarrow \text{Bool} \times \text{Bool}$ (not just $k < 4 \wedge n$), are the substantial content; everything past them is thin glue mirroring `Exercise812c.lean` line-for-line:
 1. **`xStepG_snd_eq_inter_XPseqCode/yStepG_fst_eq_inter_YPseqCode`:** generalize (b)(i)/(b)(ii) headline I-formulas from a bounded bit-source k to an arbitrary history δ , via $k := \text{encodeDeltaPair } \delta \ n$ (`atomPairG_congr` makes `atomPairG  $\delta \ n$` match `atomPairG (deltaPair k) n` exactly, since they agree on $[0, n)$). Two genuinely new sub-cases beyond (b)(i)/(b)(ii)’s own case splits: (a) the classical component itself is $\emptyset$ ($B = \emptyset/A1 = \emptyset$) — closed directly via `SplitSpec'`, no code-level content needed; (b) the “junk-mismatch” case — the classical component is non-empty (so `atomPairJunk n k = 0`, via `atomPairJunk_eq_zero_of_ne_empty/_snd_ne_empty`), yet the *half-step*’s own junk flag (`xPseqAtomJunk/yPseqAtomJunk`) is freshly 1 at exactly this (n, k) — impossible to invoke (b)(i)/(b)(ii)’s headline directly (its `junk = 0` precondition fails), so instead both sides are shown $= \emptyset$ independently: the code-level

side via unfolding `xSubStep_junk_eq/ySubStep_junk_eq` one layer to locate exactly which check tripped (`emptyInterDec/emptyDiffDec`'s own `_eq_one_iff`), the classical-intersection side via `mem_XPseqCode_iff_unconditional/mem_YPseqCode_iff_unconditional`'s existential witness `k'` necessarily being $\neq (k, \text{bx})$ (else contradicting the fresh-junk hypothesis directly), then disjoint via `atomPairCodeState_disjoint` ($k' \neq k$) or `xStepG_disjoint_of_ne` ($k' = k$, bit differs — the Y-side's extra case beyond the X-side, from the free `bx` bit).

2. `xStepG_snd_succ_eq_XPseqCode/yStepG_fst_succ_eq_YPseqCode`: complete finding 1's true-only fact into a full two-branch closed form at either sign, exactly mirroring `Exercise812c.lean`'s `xStep_snd_succ_eq/yStep_fst_succ_eq` — the false branch derived purely algebraically from the true branch plus `SplitSpec`'s $I \cup J = B/I \cap J = \emptyset$ fields, no new disjointness content.
3. Everything else (`genAtom_combinedXCode_succ_eq/_YCode_succ_eq`, `atomPairG_fst_eq_genAtomCode/_snd_eq_genAtomCode`, `hcoreCode_even/_odd/hcoreCode`) is a direct line-for-line transcription of `Exercise812c.lean`'s corresponding classical proofs, substituting finding 2's closed forms for `xStep_snd_succ_eq/yStep_fst_succ_eq` and `xStepG_spec` for `xStep_spec_bit` (`hcoreCode_odd` only ever needs the fixed-bit `xStep_spec`-level fact, not the free-`bx` generalization). `hcore/hcore_even/hcore_odd` renamed `hcoreCode/hcoreCode_even/hcoreCode_odd` to avoid a same-namespace name clash with `Exercise812c.lean`'s classical versions. Two `set_option maxHeartbeats` bumps needed (4000000 on `yStepG_fst_eq_inter_YPseqCode`); the initial heartbeat timeout was fixed not by raising the limit alone but by computing the shared `stateJunk s1 = selectFn ...` unfolding *once* (`hs1junk_eq`) and reusing it, instead of re-unfolding the same large `packState2/xSubStep` term three separate times. Zero sorry; lake build (2990 jobs) and lake env lean `Exercise812d.lean` both clean (one pre-existing harmless `linter.unusedSectionVars` warning on (b)(ii)'s dichotomy lemma, unchanged from that checkpoint). `#print axioms` on `hcoreCode`, both new I-formulas, and `yStepG_fst_succ_eq_YPseqCode` all give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section's established baseline.

Exercise 8.12(d)(5)(b)(iv): the headline transfer theorems

- **Mathematical Target:** `X_subset_iff_XPseqCode_subset/YPseqCode_subset_iff_Y_subset/X_inter_eq_iff_XPseqCode_inter_eq/YPseqCode_inter_eq_iff_Y_inter_eq` (stated on the (d)(5)(b) row above), assembled from (b)(iii)'s `hcore` via `Theorem88.lean`'s **already fully generic** `transfer_dir` (zero new general theory needed — only new *instantiations*), mirroring `Exercise812c.lean`'s own `transfer_empty_combined/transfer_subset_combined/transfer_double_subset_combined/transfer_inter_eq_combined` wrappers (lines 1494–1649), then specializing each to even/even and odd/odd index pairs via `combinedXCode_even/_odd/combinedYCode_even/_odd`.
- **Lean File:** `Exercise812d.lean` (new section `CombinedCodeTransfer`, appended)
- **Proof Notes:** direct transcription of `Exercise812c.lean`'s `transfer_empty_combined/transfer_subset_combined/transfer_double_subset_combined/transfer_inter_eq_combined/X_subset_iff_XPseq_subset/YPseq_subset_iff_Y_subset/X_inter_eq_iff_XPseq_inter_eq/YPseq_inter_eq_iff_Y_inter_eq`, substituting `combinedX  $\mapsto$  combinedXCode, combinedY  $\mapsto$  combinedYCode, hcore  $\mapsto$  hcoreCode` throughout — every proof step (the `cs-list Set.ext/tauto` bookkeeping, the `Set.not_nonempty_iff_eq_empty/not_iff_not` closing moves, `transfer_inter_eq_combinedCode`'s three-lemma `h1/h2/h3` assembly) carried over unchanged. One genuine simplification found, not available to `Exercise812c.lean`'s

classical setting: **no combinedX_subset_master-style case split on parity is needed.** Exercise812c.lean’s own combinedX_subset_master/combinedY_subset_master needed hXmem/hYmem plus a separate YPseq_subset_master/XPseq_subset_master theorem for the odd branch, since X/Y there are bare enumeration functions assumed (not proved) to be $D_0.\text{mem}/D_1.\text{mem}$ -valued, and YPseq/XPseq’s images are not literally values of X/Y. Here every value of combinedXCode/combinedYCode, at *either* parity, is literally $P_0.X _ / P_1.X _$ for some index (YPseqCode/XPseqCode are themselves $\mathbb{N}$ -valued, fed back through $P_0.X/P_1.X$), so ComputablePresentation.mem_X ($\forall n, V.\text{mem } (X \ n)$, unconditional) plus $D_0.\text{sub_master}/D_1.\text{sub_master}$ closes combinedXCode_subset_master/combinedYCode_subset_master uniformly via a single split $<;>$ exact $D_0.\text{sub_master } (P_0.\text{mem_X } _)$, with no hXmem/hYmem-style hypothesis and no separate XPseqCode_subset_master/YPseqCode_subset_master theorem needed at all. Zero sorry; lake build (3165 jobs) and lake env lean Exercise812d.lean both clean (only the pre-existing (b)(ii)-era linter.unusedSectionVars warning remains, unchanged). #print axioms on all four headline theorems gives $\subseteq \{\text{propxt}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(5)(c): cross-family order and equality facts

- **Mathematical Target:** generalizing $X_subset_YPseq_iff_XPseq_subset_Y/YPseq_subset_X_iff_Y_subset_XPseq/XPseq_eq_Y_iff_X_eq_YPseq$ ((c)(vii)(3)/(4)):

- theorem $X_subset_YPseqCode_iff_XPseqCode_subset_Y$ ($i \ j : \mathbb{N}$) : $P_0.X \ i \subseteq P_0.X \ (YPseqCode \ \dots \ j) \leftrightarrow P_1.X \ (XPseqCode \ \dots \ i) \subseteq P_1.X \ j$
- theorem $YPseqCode_subset_X_iff_Y_subset_XPseqCode$ ($i \ j : \mathbb{N}$) : $P_0.X \ (YPseqCode \ \dots \ i) \subseteq P_0.X \ j \leftrightarrow P_1.X \ i \subseteq P_1.X \ (XPseqCode \ \dots \ j)$
- theorem $XPseqCode_eq_Y_iff_X_eq_YPseqCode$ ($j \ k : \mathbb{N}$) : $P_1.X \ (XPseqCode \ \dots \ j) = P_1.X \ k \leftrightarrow P_0.X \ j = P_0.X \ (YPseqCode \ \dots \ k)$

- **Lean File:** — (not yet started)
- **Proof Notes (plan):** per (c)(vii)(3)’s own docstring, these need **no new proof machinery** beyond (d)(5)(b)’s transfer facts — direct specializations of the same interleaved-family transfer theorem at *mixed* even/odd (resp. odd/even) index pairs, simplified by the same `Set.inter_eq_self_of_subset_right` bookkeeping (c)(vii)(3) uses. `XPseqCode_eq_Y_iff_X_eq_YPseqCode` packages both cross-parity subset facts via `Set.Subset.antisymm` in each direction, exactly as `XPseq_eq_Y_iff_X_eq_YPseq` does. **Sub-part breakdown:** Exercise812c.lean’s own three theorems ((c)(vii)(3)/(4), lines 1864–1944) are already three independent, cleanly-separated proof units — two symmetric one-shot **transfer_subset_combined** specializations (each ≈ 15 lines) plus one packaging theorem consuming both — so this row is re-scoped into 3 sub-parts, (c)(i)–(c)(iii) below, matching that natural division exactly (no further design work needed, unlike (d)(5)(b)’s own re-scoping, which required a genuine investigation first).

Exercise 8.12(d)(5)(c)(i): the cross-parity order fact, even/odd mix

- **Mathematical Target:** the code-level analogue of Exercise812c.lean’s $X_subset_YPseq_iff_XPseq_subset_Y$ (lines 1864–1880):
- theorem $X_subset_YPseqCode_iff_XPseqCode_subset_Y$ ($i \ j : \mathbb{N}$) : $P_0.X \ i \subseteq P_0.X \ (YPseqCode \ \dots \ j) \leftrightarrow P_1.X \ (XPseqCode \ \dots \ i) \subseteq P_1.X \ j$

- **Lean File:** `Exercise812d.lean` (new section `CombinedCodeCrossFamily`, appended after `CombinedCodeTransfer`)
- **Proof Notes:** exactly as planned — one direct specialization of (d)(5)(b)(iv)’s `transfer_subset_combinedCode` at the mixed indices $(2i, 2j+1)$ (`combinedXCode` at an even index against `combinedYCode` at an odd index), then `rw [combinedXCode_even, combinedXCode_odd, combinedYCode_even, combinedYCode_odd, ...]` plus the same two `Set.inter_eq_self_of_subset_right` bookkeeping steps `X_subset_iff_XPseqCode_subset` already uses ($D_0.\text{sub_master } (P_0.\text{mem_X } i)$ on the left, $D_1.\text{sub_master } (P_1.\text{mem_X } (XPseqCode \dots i))$ on the right). No new lemma content, direct transcription — matched the plan exactly, no surprises. Zero sorry; lake build (3165 jobs) and lake env lean `Exercise812d.lean` both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning remains, unchanged). `#print axioms X_subset_YPseqCode_iff_XPseqCode_subset_Y` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(5)(c)(ii): the cross-parity order fact, odd/even mix

- **Mathematical Target:** the code-level analogue of `Exercise812c.lean`’s `YPseq_subset_X_iff_Y_subset_XPseq` (lines 1882–1895), symmetric to (c)(i):
 - theorem `YPseqCode_subset_X_iff_Y_subset_XPseqCode (i j : ℕ) : P0.X (YPseqCode ... i)  $\subseteq$  P0.X j  $\leftrightarrow$  P1.X i  $\subseteq$  P1.X (XPseqCode ... j)`
- **Lean File:** `Exercise812d.lean` (same section `CombinedCodeCrossFamily` as (c)(i))
- **Proof Notes:** exactly as planned — the symmetric specialization of `transfer_subset_combinedCode` at $(2i + 1, 2j)$, `rw-ing combinedXCode_odd/combinedXCode_even/combinedYCode_odd/combinedYCode_even` then the mirror-image `Set.inter_eq_self_of_subset_right` pair ($D_0.\text{sub_master } (P_0.\text{mem_X } (YPseqCode \dots i))$ on the left, $D_1.\text{sub_master } (P_1.\text{mem_X } j)$ on the right). No new lemma content, matched the plan exactly. Zero sorry; lake build (3165 jobs) and lake env lean `Exercise812d.lean` both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning remains, unchanged). `#print axioms YPseqCode_subset_X_iff_Y_subset_XPseqCode` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(5)(c)(iii): the cross-parity `embed_eq_iff` analogue

- **Mathematical Target:** the code-level analogue of `Exercise812c.lean`’s `XPseq_eq_Y_iff_X_eq_YPseq` (lines 1921–1944), needed by (d)(5)(d)’s `toD1Code/toD0Code up_mem` case to rename a covering witness back into `XPseqCode/YPseqCode` “coordinates”:
 - theorem `XPseqCode_eq_Y_iff_X_eq_YPseqCode (j k : ℕ) : P1.X (XPseqCode ... j) = P1.X k  $\leftrightarrow$  P0.X j = P0.X (YPseqCode ... k)`
- **Lean File:** `Exercise812d.lean` (same section `CombinedCodeCrossFamily` as (c)(i)/(c)(ii))
- **Proof Notes:** exactly as planned — pure packaging, no new mathematical content. Each direction is `Set.Subset.antisymm` combining (c)(i)’s `X_subset_YPseqCode_iff_XPseqCode_subset_Y` applied at (j, k) with (c)(ii)’s `YPseqCode_subset_X_iff_Y_subset_XPseqCode` applied at (k, j) (one `.mpr/.mp` on each of `h.subset/h.symm.subset`), exactly mirroring `XPseq_eq_Y_iff_X_eq_YPseq`’s four-line proof body line-for-line. Zero sorry; lake build (3165 jobs) and lake env lean `Exercise812d.lean` both clean (only

the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning remains, unchanged).
`#print axioms XPseqCode_eq_Y_iff_X_eq_YPseqCode` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(5)(d): `toD1Code/toD0Code`, the generalized elementwise maps

- **Mathematical Target:** generalizing `toD1/toD0` ((c)(vii)(4)/(5)) — tentative names, final naming deferred to execution:

```

- def toD1Code (x : D0.Element) : D1.Element where mem T := ∃ n, T = P1.X
  (XPseqCode ... n) ∧ x.mem (P0.X n); ...
- def toD0Code (y : D1.Element) : D0.Element where mem S := ∃ n, S = P0.X
  (YPseqCode ... n) ∧ y.mem (P1.X n); ...

```

- **Lean File:** — (not yet started)
- **Proof Notes (plan):** sub from `XPseqCode_mem_unconditional/YPseqCode_mem_unconditional` ((d)(4), already Pass); `master_mem` from (d)(5)(a)’s zero facts at $n = 0$; **inter_mem simplified per finding 3 — no exists_inter_index_X/Y-analogue or hXcover/hYcover hypothesis needed**, cite `P1.inter i j / P1.inter_spec` (resp. `P0.inter`) directly (`x.sub (x.inter_mem hxi hxj)` gives the consistency witness `inter_spec` needs); `up_mem` from (d)(5)(c)’s cross-family facts plus `P0.surj / P1.surj` (Definition 7.1, replacing (c)(vii)’s assumed `hXcover/hYcover` — another simplification, since `ComputablePresentation.surj` already *is* the covering fact, no separate hypothesis needed), transcribing `toD1/toD0`’s `up_mem` proof body directly.

- **A second, sharper simplification found (2026-07-05, on close inspection before executing):** `up_mem`’s *own* body needs only *one* `surj` call, not two. `Exercise812c.lean`’s `toD1.up_mem` performs *two* renamings: first `hYcover` `T2` names the arbitrary target `T2` as some `Y k`; then, after transporting `x`’s membership across via the cross-parity order fact, `hXcover` renames the *resulting* set `YPseq k` as some fresh `X j` (needed only because `YPseq k`, a priori just some `D0.mem` set, is not *literally* a value of the enumeration `X` — genuine search required). At the code level this second search is **not needed**: `YPseqCode/XPseqCode` are already `N`-valued, so `P0.X (YPseqCode ... k)` (resp. `P1.X (XPseqCode ... k)`) is *already*, syntactically, `P0.X j` for the explicit witness `j := YPseqCode ... k` — no covering search is needed to “find” it, it is handed over for free. The only remaining obligation is the *equation* linking this free index back to the original target index `k` (i.e. `P1.X k = P1.X (XPseqCode ... (YPseqCode ... k))`, resp. `P0.X k = P0.X (YPseqCode ... (XPseqCode ... k))`), and this drops out of (c)(iii)’s `XPseqCode_eq_Y_iff_X_eq_YPseqCode` applied at the *self-referential* pair `(YPseqCode ... k, k)` (resp. `(k, XPseqCode ... k)`), whose “other side” is trivially `rfl (P0.X (YPseqCode ... k) = P0.X (YPseqCode ... k))`, resp. `P1.X (XPseqCode ... k) = P1.X (XPseqCode ... k)`). So `toD1Code/toD0Code`’s `up_mem` needs exactly *one* `P0.surj / P1.surj` call each (to name the arbitrary target `T2/S2` as some code-level index in the first place), not two — a genuine simplification over `Exercise812c.lean`’s two-search argument, verified by hand-tracing the full proof term before writing any Lean.

- **Sub-part breakdown:** re-scoped into 4 sub-parts, (d)(5)(d)(i)–(iv) below, mirroring `Exercise812c.lean`’s own `Element`-field structure: the two easy fields (`sub`, `master_mem`) and the `inter_mem/up_mem` fields all being one-liners except `up_mem` (the only field needing genuinely chained reasoning), each half (`toD1Code`, `toD0Code`) is split into its own standalone `up_mem` helper lemma — stated at the literal type the `Element.up_mem` field

needs, so it plugs directly into the final structure literal — followed by the full assembly `def` (which discharges `sub/master_mem/inter_mem` inline, since each really is a one-liner not worth its own row).

Exercise 8.12(d)(5)(d)(i): `toD1Code`'s `up_mem` helper

- **Mathematical Target:** the standalone lemma capturing `toD1Code`'s `up_mem` field content, stated at the exact type `Element.up_mem` needs for the predicate `fun T => ∃ n, T = P1.X (XPseqCode ... n) ∧ x.mem (P0.X n)`:

```

- theorem toD1Code_up_mem (x : D0.Element) {T1 T2 : Set β} (h1 : ∃ n, T1
  = P1.X (XPseqCode ... n) ∧ x.mem (P0.X n)) (hD1T2 : D1.mem T2) (hT1T2 :
  T1 ⊆ T2) : ∃ n, T2 = P1.X (XPseqCode ... n) ∧ x.mem (P0.X n)

```

- **Lean File:** `Exercise812d.lean` (new section `ToD1CodeUpMem`, appended after `CombinedCodeCrossFam`)
- **Proof Notes:** matched the plan exactly, first try, no surprises. Destructure `h1` as $\langle i, \text{rfl}, \text{hxi} \rangle$; `P1.surj hD1T2` names `T2` as some `P1.X k` (`subst hk` substitutes `T2 := P1.X k` directly, since `hk : P1.X k = T2` still `subst`s cleanly regardless of orientation); `(d)(5)(c)(i)`'s `X_subset_YPseqCode_iff_XPseqCode_subset_Y i k` turns `hT1T2 : P1.X (XPseqCode ... i) ⊆ P1.X k` into `P0.X i ⊆ P0.X (YPseqCode ... k)`; `x.up_mem hxi (YPseqCode_mem_unconditional k)` this gives `x.mem (P0.X (YPseqCode ... k))` — already literally `x.mem (P0.X j)` for `j := YPseqCode ... k`, no further covering search needed (confirming the parent row's second simplification); close with witness `j` via `(d)(5)(c)(iii)`'s `XPseqCode_eq_Y_iff_X_eq_YPseqCode (YPseqCode ... k) k` `>|.mpr rfl : P1.X (XPseqCode ... (YPseqCode ... k)) = P1.X k`, `.symm`'d to match the goal's `T2 = P1.X (XPseqCode ... j)` orientation. Zero sorry; lake build (3165 jobs) and lake env lean `Exercise812d.lean` both clean (only the pre-existing `(b)(ii)`-era `linter.unusedSection` warning remains, unchanged). `#print axioms toD1Code_up_mem` gives `⊆ {propext, Classical.choice, Quot.sound}`, matching this section's established baseline.

Exercise 8.12(d)(5)(d)(ii): `toD1Code`, full assembly

- **Mathematical Target:** the `D0.Element → D1.Element` pushforward map itself:

```

- def toD1Code (x : D0.Element) : D1.Element where mem T := ∃ n, T = P1.X
  (XPseqCode ... n) ∧ x.mem (P0.X n); ...

```

- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (new section `ToD1Code`, appended after `ToD1CodeUpMem`)
- **Proof Notes:** matched the plan's `sub/master_mem/up_mem` fields exactly (`sub := fun ⟨n, hn, _⟩ => hn ▶ XPseqCode_mem_unconditional ... n; master_mem := ⟨0, (XPseqCode_zero ... hX0).symm, by rw [hX0]; exact x.master_mem⟩`; `up_mem := toD1Code_up_mem ... x`), but `inter_mem` needed a real (if short) argument, not the one-line citation the plan sketched: the plan's `P1.inter i j / P1.inter_spec` witness doesn't type-check (`P1.inter i j` indexes *into* `P1`, but the shared witness `n` in `toD1Code`'s `mem T := ∃ n, T = P1.X (XPseqCode ... n) ∧ x.mem (P0.X n)` must be a `P0`-side index, since it feeds `x.mem (P0.X n)`). The correct witness is `P0.inter i j`: `x.inter_mem hxi hxj / x.sub` show `P0.X i ∩ P0.X j` is already `D0`-genuine, so `P0.surj` names it as some `P0.X m` outright (`hm.le` supplies the $\exists k, X k \subseteq X i \cap X j$ consistency witness `P0.inter_spec` needs, no search beyond `surj`), giving the closed-form `P0.X (P0.inter i j) = P0.X i ∩ P0.X j`; `(d)(5)(b)(iv)`'s `X_inter_eq_iff_XPseqCode_inter_eq` (`.symm`'d

for orientation) transports this same equation across to `XPseqCode`, landing exactly the first conjunct needed. Still **no exists_inter_index_X**-style covering-search helper needed (the parent row’s finding 3 confirmed, just via `P0.inter/P0.surj` rather than `P1.inter/P1.surj`). Built clean on the corrected version (`lake build` — 3165 jobs — and `lake env lean Exercise812d.lean` directly, both clean; only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning remains, unchanged). Zero sorry. Axiom-audited: `toD1Code` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(5)(d)(iii): `toD0Code`’s `up_mem` helper

- **Mathematical Target:** the mirror of (d)(5)(d)(i) for the $D_1 \rightarrow D_0$ direction:
 - theorem `toD0Code_up_mem` ($y : D_1.\text{Element}$) $\{S1\ S2 : \text{Set } \alpha\}$ ($h1 : \exists n, S1 = P_0.X\ (\text{YPseqCode } \dots n) \wedge y.\text{mem}\ (P_1.X\ n)$) ($hD0S2 : D_0.\text{mem}\ S2$) ($hS1S2 : S1 \subseteq S2$) : $\exists n, S2 = P_0.X\ (\text{YPseqCode } \dots n) \wedge y.\text{mem}\ (P_1.X\ n)$
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (new section `ToD0CodeUpMem`, appended after `ToD1Code`)
- **Proof Notes:** exact mirror of (d)(5)(d)(i), matched the plan on the first try with no surprises: destructure `h1` as $\langle i, \text{rfl}, \text{hyi} \rangle$; `P0.surj hD0S2` names `S2` as some `P0.X k` (`subst hk`); (d)(5)(c)(ii)’s `YPseqCode_subset_X_iff_Y_subset_XPseqCode i k` turns `hS1S2 : P0.X (YPseqCode ... i)  $\subseteq$  P0.X k` into `P1.X i  $\subseteq$  P1.X (XPseqCode ... k)`; `y.up_mem hyi (XPseqCode_mem_unconditional ... k)` this gives `y.mem (P1.X (XPseqCode ... k))` — already literally `y.mem (P1.X j)` for $j := \text{XPseqCode } \dots k$, no covering search needed; closes with witness `j` via (d)(5)(c)(iii)’s `XPseqCode_eq_Y_iff_X_eq_YPseqCode k (XPseqCode ... k) |>.mp rfl : P0.X k = P0.X (YPseqCode ... (XPseqCode ... k))`, matching the goal’s `S2 = P0.X (YPseqCode ... j)` orientation directly with **no .symm needed** (unlike `toD1Code_up_mem`, where the mirror-image goal orientation did need one). Built clean (`lake build` — 3165 jobs — and `lake env lean Exercise812d.lean` directly, both clean; only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning remains, unchanged). Zero sorry. Axiom-audited: `toD0Code_up_mem` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(5)(d)(iv): `toD0Code`, full assembly

- **Mathematical Target:** the $D_1.\text{Element} \rightarrow D_0.\text{Element}$ pullback map, mirror of (d)(5)(d)(ii):
 - def `toD0Code` ($y : D_1.\text{Element}$) : $D_0.\text{Element}$ where `mem S` := $\exists n, S = P_0.X\ (\text{YPseqCode } \dots n) \wedge y.\text{mem}\ (P_1.X\ n)$; ...
- **Lean File:** `Scott1980/Neighborhood/Exercise812d.lean` (new section `ToD0Code`, appended after `ToD0CodeUpMem`)
- **Proof Notes:** `sub/master_mem/up_mem` matched the plan exactly (`YPseqCode_mem_unconditional/YPseqCode_zero` at $n = 0$ with `hY0/toD0Code_up_mem y`). **inter_mem needed the same style of correction as (d)(5)(d)(ii)’s `toD1Code`, with `P0/P1` swapped:** the witness must be `P1.inter i j` (not `P0.inter i j`), since `toD0Code`’s shared index `n` in $\exists n, S = P_0.X\ (\text{YPseqCode } \dots n) \wedge y.\text{mem}\ (P_1.X\ n)$ feeds `y.mem (P1.X n)`, a `P1-side` fact. `y.inter_mem hyi hyj/y.sub` show `P1.X i  $\cap$  P1.X j` is `D1-genuine`, `P1.surj` names it as some `P1.X m` (`hm.le` supplies the consistency witness `P1.inter_spec` needs), giving `P1.X (P1.inter i j) = P1.X i  $\cap$  P1.X j`; (d)(5)(b)(iv)’s `YPseqCode_inter_eq_iff_Y_inter_eq` transports this to `YPseqCode`. **One extra wrinkle beyond**

toD1Code's mirror: `YPseqCode_inter_eq_iff_Y_inter_eq`'s iff has the `YPseqCode`-side on the *left* (opposite of `X_inter_eq_iff_XPseqCode_inter_eq`'s orientation), so closing the goal needs `.mpr hinterEq.symm`, not `.mp hinterEq` — the asymmetry was anticipated from the previous checkpoint's resume note and confirmed correct on the first build attempt. Built clean (`lake build` — 3165 jobs — and `lake env lean Exercise812d.lean` directly, both clean; only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning remains, unchanged). Zero sorry. Axiom-audited: `toD0Code` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section's established baseline.

Exercise 8.12(d)(5)(e): `domainIsoCode812d`, the generalized order isomorphism

- **Mathematical Target:** generalizing `domainIso812c/isomorphic_812c ((c)(vii)(6))`:

- theorem `X_eq_iff_XPseqCode_eq (i j : ℕ) : P0.X i = P0.X j ↔ P1.X (XPseqCode ... i) = P1.X (XPseqCode ... j)` (same-family “`embed_eq_iff`” companion, needed by `map_rel_iff'`, packaged from (d)(5)(b)'s subset facts via `Set.Subset.antisymm` in each direction, mirroring `X_eq_iff_XPseq_eq`)
- noncomputable def `domainIsoCode812d : DomainIso D0 D1 where toFun := toD1Code ...; invFun := toD0Code ...; left_inv := ...; right_inv := ...; map_rel_iff' := ...`
- theorem `isomorphic_812d : D0 ≅D D1 := ⟨domainIsoCode812d ...⟩`

- **Lean File:** — (not yet started); umbrella — see sub-rows 8.12(d)(5)(e)(i)–(iv) below, re-scoped 2026-07-05 before executing (mirroring how (d)(5)(d) was scoped before its own code)
- **Proof Notes:** Re-scoping investigation, done before writing any code, comparing against `Exercise812c.lean`'s actual `domainIso812c` (lines 2049–2116: `toFun/invFun/left_inv/right_inv/map_rel_iff'`, ~70 lines total, `X_eq_iff_XPseq_eq (c)(vii)(6)` as a short standalone lemma beside it) and against (d)(5)(d)'s own just-completed `toD1Code/toD0Code` precedent (the “one `surj` call, no covering search, close via a self-referential `XPseqCode_eq_Y_iff_X_eq_YPseqCode` application” pattern that made `up_mem/inter_mem` short at the code level despite their classical counterparts needing `hXcover/hYcover` searches):

1. `left_inv/right_inv` are genuinely two-directional mutual-inverse content, not one-liners, but the same `up_mem`-style simplification applies to them, hand-traced below. `domainIso812c.left_inv x` (`Exercise812c.lean` lines 2054–2073) needs **two** covering searches per direction (`hXcover/hYcover`, mirroring `toD1.up_mem`'s two-search argument) to show `toD0 (toD1 x) = x` as `Elements`. At the code level, hand-tracing `toD0Code (toD1Code x) = x` (via `Element.ext`, unfolding both `mem` predicates to $\exists m\ n, S = P_0.X (YPseqCode \dots m) \wedge P_1.X m = P_1.X (XPseqCode \dots n) \wedge x.mem (P_0.X n) \leftrightarrow x.mem S$) shows it collapses to **one** `P0.surj` call exactly as `toD1Code.up_mem` did: given `x.mem S`, `x.sub/P0.surj` names `S` as some `P0.X n` outright; take `m := XPseqCode ... n` (handed over for free, no search); `P1.X m = P1.X (XPseqCode ... n)` is `rfl`; and (d)(5)(c)(iii)'s `XPseqCode_eq_Y_iff_X_eq_YPseqCode n (XPseqCode ... n) |>.mpr rfl : P0.X n = P0.X (YPseqCode ... (XPseqCode ... n))` supplies the closing `S = P0.X (YPseqCode ... m)` equation for free. The converse direction (consuming an arbitrary witness `⟨m, n, hS, hmn, hxn⟩`) is pure bookkeeping: `XPseqCode_eq_Y_iff_X_eq_YPseqCode n m` transports `hmn` into `P0.X n = P0.X (YPseqCode ... m)`, combines with `hS` to get `S = P0.X n`, and rewrites `hxn` into `x.mem S`. `right_inv (toD1Code (toD0Code y) = y)` is the exact mirror via `P1.surj/YPseqCode ... m := YPseqCode-then-XPseqCode`.

2. **map_rel_iff'** needs the same one-search simplification. `domainIso812c.map_rel_iff'` (lines 2094–2108) splits into an easy `mpr` direction ($x \leq x2 \rightarrow \text{toD1 } x \leq \text{toD1 } x2$, pure unfolding, no search) and a harder `mp` direction ($\text{toD1 } x \leq \text{toD1 } x2 \rightarrow x \leq x2$) needing `hXcover` to name an arbitrary S with $x.\text{mem } S$ as some $X \ n$, then `hle` at `XPseq n` plus `X_eq_iff_XPseq_eq` to transport the resulting index equality back to S . At the code level the `hXcover` search is again just `P0.surj`, and `X_eq_iff_XPseqCode_eq` (finding 3 below) plays `X_eq_iff_XPseq_eq`'s role — no other change needed, direct transcription otherwise.
 3. **X_eq_iff_XPseqCode_eq** itself is a clean, short packaging lemma, exactly mirroring `X_eq_iff_XPseq_eq` — `Set.Subset.antisymm` of (d)(5)(b)'s `X_subset_iff_XPseqCode_subset` applied in each direction ($i \ j/j \ i$), no new content.
- **Sub-part breakdown:** re-scoped into 4 sub-parts, (e)(i)–(iv) below, mirroring (d)(5)(d)'s helper-lemma-then-assembly pattern (applied here to `left_inv/right_inv` instead of `up_mem`, one standalone lemma per direction) plus a leading small packaging lemma and a trailing full assembly: (e)(i) the `X_eq_iff_XPseqCode_eq` packaging lemma (finding 3); (e)(ii)/(e)(iii) the `left_inv/right_inv` mutual-inverse content as standalone lemmas (finding 1), one per direction; (e)(iv) the full `domainIsoCode812d/isomorphic_812d` assembly, discharging `toFun/invFun/map_rel_iff'` inline (the latter short enough per finding 2 not to need its own row, same call as (d)(5)(d)(ii)'s `inter_mem`) and citing (e)(ii)/(e)(iii) for `left_inv/right_inv`.

Exercise 8.12(d)(5)(e)(i): `X_eq_iff_XPseqCode_eq`, the same-family `embed_eq_iff` companion

- **Mathematical Target:** theorem `X_eq_iff_XPseqCode_eq (i j : ℕ) : P0.X i = P0.X j ↔ P1.X (XPseqCode ... i) = P1.X (XPseqCode ... j)`, needed by (e)(iv)'s `map_rel_iff'`
- **Lean File:** `Exercise812d.lean` (new section `XEqIffXPseqCodeEq`, appended after `ToD0Code`)
- **Proof Notes:** matched the plan exactly, first try, no surprises — direct transcription of `Exercise812c.lean`'s `X_eq_iff_XPseq_eq` (lines 2027–2041): each direction is `Set.Subset.antisymm` of (d)(5)(b)(iv)'s `X_subset_iff_XPseqCode_subset` applied at (i, j) and (j, i) (`.mp/.mpr` on `h.subset/h.symm.subset`), no new mathematical content. Zero sorry; lake build Scott1980 (3165 jobs) and lake env lean `Exercise812d.lean` both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning on `yPseqAtomIdx_eq_of_dichotomy` remains, unchanged). `#print axioms X_eq_iff_XPseqCode_eq` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section's established baseline (choice inherited from `splitChoice'/atomPairG`-family precedents, no new taint).

Exercise 8.12(d)(5)(e)(ii): the `left_inv` content, `toD0Code (toD1Code x) = x`

- **Mathematical Target:** theorem `toD0Code_toD1Code (x : D0.Element) : toD0Code ... (toD1Code ... x) = x`, the standalone lemma feeding `domainIsoCode812d`'s `left_inv` field
- **Lean File:** `Exercise812d.lean` (new section `ToD0CodeToD1Code`, appended after `XEqIffXPseqCodeEq`)
- **Proof Notes:** matched the plan exactly, first try, no surprises. Via `Element.ext/intro S/constructor`, reduces to $(\exists m \ n, S = P_0.X (YPseqCode \dots m) \wedge P_1.X m = P_1.X$

($\text{XPseqCode} \dots n \wedge x.\text{mem} (P_0.X \ n) \leftrightarrow x.\text{mem} \ S.\text{Forward}(\text{mp}, \text{rintro} \langle m, hS, n, \text{hmn}, \text{hxn} \rangle)$): (d)(5)(c)(iii)'s $\text{XPseqCode_eq_Y_iff_X_eq_YPseqCode} \ n \ m$ applied to $\text{hmn}.\text{symm}$ gives $\text{hXeq} : P_0.X \ n = P_0.X \ (\text{YPseqCode} \dots m)$; $\text{rw} [\text{hS}, \leftarrow \text{hXeq}]$ reduces the goal $x.\text{mem} \ S$ to $x.\text{mem} (P_0.X \ n)$, closed by hxn . $\text{Backward}(\text{mpr}, \text{intro} \ \text{hxS})$: $x.\text{sub}/P_0.\text{surj}$ names S as some $P_0.X \ n$ outright, and (unlike $\text{toD1Code_up_mem}/\text{toD0Code_up_mem}$, which used $\text{subst} \ \text{hk}$ on an equation of the form $P.X \ k = T$) $\text{subst} \ \text{hn}$ here directly rewrites hxS into $x.\text{mem} (P_0.X \ n)$ in place — no separate have needed; witness $m := \text{XPseqCode} \dots n$ (handed over for free, no search, $P_1.X \ m = P_1.X \ (\text{XPseqCode} \dots n)$ literally rfl); the closing equation $P_0.X \ n = P_0.X \ (\text{YPseqCode} \dots m)$ is $\text{XPseqCode_eq_Y_iff_X_eq_YPseqCode} \ n \ (\text{XPseqCode} \dots n) \mid >.\text{mpr} \ \text{rfl}$ at the self-referential pair, exactly toD1Code_up_mem 's pattern — confirming no $\text{hXcover}/\text{hYcover}$ -style double search is needed, unlike $\text{domainIso812c.left_inv}$'s own proof. Zero sorry; lake build Scott1980 (3165 jobs) and lake env lean Exercise812d.lean both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning on `yPseqAtomIdx_eq_of_dichotomy` remains, unchanged). `#print axioms toD0Code_toD1Code` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section's established baseline.

Exercise 8.12(d)(5)(e)(iii): the `right_inv` content, `toD1Code (toD0Code y) = y`

- **Mathematical Target:** theorem `toD1Code_toD0Code (y : D1.Element) : toD1Code ... (toD0Code ... y) = y`, the standalone lemma feeding `domainIsoCode812d`'s `right_inv` field, exact mirror of (e)(ii)
- **Lean File:** `Exercise812d.lean` (new section `ToD1CodeToD0Code`, appended after `ToD0CodeToD1Code`)
- **Proof Notes:** exact mirror of (e)(ii)'s `toD0Code_toD1Code`, matched on the first try, with **one genuine orientation asymmetry found (as anticipated by (e)(ii)'s own resume note)**: via `Element.ext/intro T/constructor`, reduces to $(\exists m \ n, T = P_1.X \ (\text{XPseqCode} \dots m) \wedge P_0.X \ m = P_0.X \ (\text{YPseqCode} \dots n) \wedge y.\text{mem} (P_1.X \ n)) \leftrightarrow y.\text{mem} \ T.\text{Forward}(\text{rintro} \langle m, hT, n, \text{hmn}, \text{hyn} \rangle)$: $\text{XPseqCode_eq_Y_iff_X_eq_YPseqCode} \ m \ n$ applied *directly* to hmn (**no `.symm` needed here**, unlike `toD0Code_toD1Code`'s forward direction — hmn 's orientation already matches the lemma's RHS) gives $\text{hYeq} : P_1.X \ (\text{XPseqCode} \dots m) = P_1.X \ n$; $\text{rw} [\text{hT}, \text{hYeq}]$; exact hyn closes it. $\text{Backward}(\text{intro} \ \text{hyT})$: $y.\text{sub}/P_1.\text{surj}$ names T as some $P_1.X \ n$ ($\text{subst} \ \text{hn}$ rewrites hyT in place); witness $m := \text{YPseqCode} \dots n$ handed over for free ($P_0.X \ m = P_0.X \ (\text{YPseqCode} \dots n)$ is rfl); the closing equation needs $\text{XPseqCode_eq_Y_iff_X_eq_YPseqCode} \ (\text{YPseqCode} \dots n) \ n \mid >.\text{mpr} \ \text{rfl}$ then **`.symm`** (unlike `toD0Code_toD1Code`'s backward direction, which needed no `.symm` — the asymmetry mirrors `toD1Code_up_mem/toD0Code_up_mem`'s own `.symm/no-.symm` split from (d)(5)(d)). Zero sorry; lake build Scott1980 (3165 jobs) and lake env lean Exercise812d.lean both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning on `yPseqAtomIdx_eq_of_dichotomy` remains, unchanged). `#print axioms toD1Code_toD0Code` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section's established baseline.

Exercise 8.12(d)(5)(e)(iv): `domainIsoCode812d/isomorphic_812d`, full assembly

- **Mathematical Target:** noncomputable `def domainIsoCode812d : DomainIso D0 D1` where `toFun := toD1Code ...`; `invFun := toD0Code ...`; `left_inv := toD0Code_toD1Code ...`; `right_inv := toD1Code_toD0Code ...`; `map_rel_iff' := ...` and theorem `isomorphic_812d : D0  $\cong^D$  D1 :=  $\langle \text{domainIsoCode812d} \dots \rangle$`
- **Lean File:** `Exercise812d.lean` (new section `DomainIsoCode812d`, appended after `ToD1CodeToD0Code`)

- **Proof Notes:** matched the plan exactly — `toFun/invFun/left_inv/right_inv` are direct citations of (d)(5)(d)’s `toD1Code/toD0Code` and (e)(ii)/(e)(iii)’s `toD0Code/toD1Code/toD1Code_toD0Code`; `map_rel_iff'` is a direct transcription of `Exercise812c.lean`’s `domainIso812c.map_rel_iff'` (lines 2094–2108): the easy `mpr` direction ($x \leq x2 \rightarrow \text{toD1Code } x \leq \text{toD1Code } x2$) is pure unfolding, no search; the harder `mp` direction ($\text{toD1Code } x \leq \text{toD1Code } x2 \rightarrow x \leq x2$) needs only *one* `P0.surj` call (subst-ing the target `S` as some `P0.X n` directly, replacing `hXcover`’s search) plus (e)(i)’s `X_eq_iff_XPseqCode_eq` to transport the resulting `XPseqCode`-index equality (from `hle`’s output) back to `P0.X`-coordinates. `isomorphic_812d` is a one-line `<domainIsoCode812d ...>` packaging, mirroring `isomorphic_812c`. **One genuine wrinkle, not anticipated by the plan:** the `include ...` in lines for `domainIsoCode812d/isomorphic_812d` needed `hDiff0/hDiff1/hSplitX/hSplitY` added explicitly (beyond the `hD0pos ...hUnion1 hX0 hY0` list that sufficed for every earlier (d)(5) theorem) — those four are never forced into scope transitively (unlike `P0/P1/splitX/splitY`, which *are* pulled in automatically since they appear in the *types* of already-included hypotheses like `hUnion0 : IsComputableUnion P0/hXSplit : SplitSpec' D1 splitX`), yet the proof terms cite `hDiff0/hDiff1/hSplitX/hSplitY` directly (as arguments to `toD1Code/toD0Code/X_eq_iff_XPseqCode_eq`), triggering “unknown identifier” until added — fixed by prepending them to both `include` lists. Zero sorry; lake build `Scott1980` (3165 jobs) and lake `env lean Exercise812d.lean` both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning on `yPseqAtomIdx_eq_of_dichotomy` remains, unchanged). `#print axioms domainIsoCode812d/isomorphic_812d` both give $\subseteq \{\text{propext, Classical.choice, Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(5)(f): computability — the exercise’s literal target

- **Mathematical Target:** `IsComputableMap P0 P1 (ofIso domainIsoCode812d)` and `IsComputableMap P1 P0 (ofIso domainIsoCode812d.symm)` — this sub-part’s (and (d)(5)’s) actual head-line statement, everything above being prerequisite plumbing:
 - theorem `toD1Code_rel_iff (n m : ℕ) : (ofIso (domainIsoCode812d ...)).rel (P0.X n) (P1.X m) ↔ ∃ k, P1.X m = P1.X (XPseqCode ... k) ∧ P0.X n ⊆ P0.X k` (mirroring `isoInj_rel_iff_incl`)
 - theorem `toD0Code_rel_iff (m n : ℕ) : (ofIso (domainIsoCode812d ...)).symm.rel (P1.X m) (P0.X n) ↔ ∃ k, P0.X n = P0.X (YPseqCode ... k) ∧ P1.X m ⊆ P1.X k` (mirroring `isoProj_rel_iff_incl`)
 - theorem `domainIsoCode812d_isComputableMap : IsComputableMap P0 P1 (ofIso (domainIsoCode812d ...))`
 - theorem `domainIsoCode812d_symm_isComputableMap : IsComputableMap P1 P0 (ofIso (domainIsoCode812d ...).symm)`
- **Lean File:** — (not yet started)
- **Re-scoping investigation (2026-07-05),** done before writing any code, hand-tracing the exact unfolding against `Approximable.lean`’s `ofIso/Basic.lean`’s `mem_principal` and `Definition72.lean`’s `comp_isComputable/apply_isComputableElement` (the *actual* r.e.-existential-closure precedent — see finding 2 below, correcting this row’s own original proof-note):
 1. `toD1Code_rel_iff`’s unfolding confirmed by hand. $(\text{ofIso } e).rel \ X \ Y := \exists _ : D_0.\text{mem } X, (e \ (D_0.\text{principal } \langle D_0.\text{mem } X \rangle)).\text{mem } Y \ (\text{Approximable.lean}). \text{At } X := P_0.X \ n, e := \text{domainIsoCode812d}, e \ (D_0.\text{principal } hXn) = \text{toD1Code } \dots$

($D_0.\text{principal } hXn$) (since $\text{domainIsoCode812d.toFun} = \text{toD1Code } \dots$), whose mem predicate ($(d)(5)(d)(ii)$) is $\text{fun } T \Rightarrow \exists k, T = P_1.X \text{ (XPseqCode } \dots k) \wedge (D_0.\text{principal } hXn).\text{mem } (P_0.X k)$; mem_principal turns the inner membership into $D_0.\text{mem } (P_0.X k) \wedge P_0.X n \subseteq P_0.X k$, and $D_0.\text{mem } (P_0.X k)$ is automatically $P_0.\text{mem_X } k$ (droppable). Net: $(\text{ofIso domainIsoCode812d}).\text{rel } (P_0.X n) (P_1.X m) \leftrightarrow \exists k, P_1.X m = P_1.X \text{ (XPseqCode } \dots k) \wedge P_0.X n \subseteq P_0.X k$, exactly the stated target — confirms the plan’s claimed shape is correct, and the proof is a short, direct unfold (no search, no case split), genuinely mirroring `Theorem88n.lean’s isoInj_rel_iff_incl/isoProj_rel_iff_incl` proof *shape* (unfold of `Iso`/the map’s mem field/ mem_principal , constructor, `rintro/exact`). `toD0Code_rel_iff` is the exact mirror via $\text{domainIsoCode812d.symm.toFun} = \text{domainIsoCode812d.invFun} = \text{toD0Code } \dots$.

2. **Correction to this row’s own original proof-note: the computability half does *not* mirror `isoInj_isComputableMap`’s proof shape “line-for-line”.** `isoInj_isComputableMap` (`Theorem88n.lean`) has *no* unbounded existential in its target relation (`isoInj_rel_iff_incl`’s RHS is the bare inclusion $P.X a \subseteq P.X (\text{eIdx } P b)$, since `eIdx` is a deterministic involution supplying the *unique* witness directly) — its proof is a single `RecDecidable.of_iff/.re` step. Our `toD1Code_rel_iff`’s RHS, by contrast, retains a **genuine unbounded** $\exists k$ (`XPseqCode` is not known to be surjective/invertible the way `eIdx` is), so the correct precedent is `Definition72.lean’s comp_isComputable/apply_isComputableElement`: reindex the two decidable pieces ($P_1.X m = P_1.X \text{ (XPseqCode } \dots k) \text{ — } P_1.\text{eq_computable}$ reindexed along the primitive-recursive `XPseqCode` via `RecDecidable.comp/primrec_XPseqCode`, $(d)(4)(c)$; $P_0.X n \subseteq P_0.X k \text{ — } P_0.\text{incl_computable}$ directly) up to `REPred` via `.re`, combine with `REPred.and`, and close the outer $\exists k$ with `REPred.proj`, then `REPred.of_iff` to match `toD1Code_rel_iff`’s exact shape — mirroring `comp_isComputable’s (hf'.comp hgf).and (hg'.comp hgg)).proj` assembly line-for-line, not `isoInj_isComputableMap`’s single-step `RecDecidable.re`. Symmetric for `domainIsoCode812d_symm_isComputableMap` via `toD0Code_rel_iff/YPseqCode/P_0.eq_computable/P_1.incl_computable`.
3. **Once this lands, (d)(5) is complete** and (d)(6) (final `EffectiveIso` assembly) becomes close to immediate, per (d)(6)’s own (corrected) proof note.

- **Sub-part breakdown:** re-scoped into 4 sub-parts, (f)(i)–(iv) below, mirroring (d)(5)(d)’s per-direction pairing (one `rel_iff` lemma then one `IsComputableMap` theorem consuming it, done twice — once per direction) rather than (d)(5)(e)’s single dependent chain, since the two directions (`toD1Code/toD0Code`) are otherwise fully independent of each other here: (f)(i) `toD1Code_rel_iff`; (f)(ii) `domainIsoCode812d_isComputableMap` (depends on (f)(i)); (f)(iii) `toD0Code_rel_iff` (mirror of (f)(i), independent of (f)(ii)); (f)(iv) `domainIsoCode812d_symm_isComputableMap` (depends on (f)(iii), mirror of (f)(ii)).

Exercise 8.12(d)(5)(f)(i): `toD1Code_rel_iff`

- **Mathematical Target:** theorem `toD1Code_rel_iff (n m : ℕ) : (ofIso (domainIsoCode812d ...)).rel (P_0.X n) (P_1.X m) ↔ ∃ k, P_1.X m = P_1.X (XPseqCode ... k) ∧ P_0.X n ⊆ P_0.X k`
- **Lean File:** `Exercise812d.lean` (new section `ToD1CodeRelIff`, appended after `DomainIsoCode812d`)
- **Proof Notes:** matched the plan exactly, first try, no surprises — the only wrinkle was that the file’s open `NeighborhoodSystem Domain.Recursive` line lacked `ApproximableMap`

(needed for the bare identifier `ofIso`, which `Theorem88n.lean` gets via its own `open ... ApproximableMap`); fixed once, project-wide, at the top of `Exercise812d.lean`. The proof itself is a direct transcription of `Theorem88n.lean`'s `isoInj_rel_iff_incl` shape: `show (∃ _ : D0.mem (P0.X n), (toD1Code ... (D0.principal (P0.mem_X n))).mem (P1.X m)) ↔ _, simp only [toD1Code, mem_principal], then constructor/rintro ⟨-, k, hk, -, hsub⟩ ↦ ⟨k, hk, hsub⟩ and rintro ⟨k, hk, hsub⟩ ↦ ⟨P0.mem_X n, k, hk, P0.mem_X k, hsub⟩ — no search, no case split, exactly as scoped. Zero sorry; lake build Scott1980 (3165 jobs) and lake env lean Exercise812d.lean both clean (only the pre-existing (b)(ii)-era linter.unusedSectionVars warning on yPseqAtomIdx_eq_of_dichotomy remains, unchanged). #print axioms toD1Code_rel_iff gives $\subseteq \{\text{propxt}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section's established baseline.`

Exercise 8.12(d)(5)(f)(ii): `domainIsoCode812d_isComputableMap`

- **Mathematical Target:** `theorem domainIsoCode812d_isComputableMap : IsComputableMap P0 P1 (ofIso (domainIsoCode812d ...))`
- **Lean File:** `Exercise812d.lean` (new section `DomainIsoCode812dIsComputableMap`, appended after `ToD1CodeRelIff`)
- **Proof Notes:** matched the plan closely, one import fix needed. `IsComputableMap P0 P1 f = REPred2 (fun n m => f.rel (P0.X n) (P1.X m))` (Definition 7.2); via (f)(i)'s `toD1Code_rel_iff`, reduces to `REPred2 (fun n m => ∃ k, P1.X m = P1.X (XPseqCode ... k) ∧ P0.X n ⊆ P0.X k)`. Built via `Definition72.lean`'s `comp_isComputable`-style existential-closure recipe: `hA : RecDecidable (fun w => P1.X w.unpair.2.unpair.2 = P1.X (XPseqCode ... w.unpair.1))` via `RecDecidable.of_iff/P1.eq_computable.comp hg` (`hg` the primitive-recursive `fun w => Nat.pair w.unpair.2.unpair.2 (XPseqCode ... w.unpair.1)`, built from `primrec_XPseqCode ((d)(4)(c))`); `hB : RecDecidable (fun w => P0.X w.unpair.2.unpair.1 ⊆ P0.X w.unpair.1)` via `RecDecidable.of_iff/P0.incl_computable.comp hh`; `(hA.and hB).re.proj` closes the outer $\exists k$ (the search variable becomes the *first* component of the paired index `w`, with `w.unpair.2` the original (n,m) -pair `t` — exactly `REPred.proj`'s $\exists i, p$ (`Nat.pair i n`) shape); final `REPred.of_iff`, after a `show` to unfold `IsComputableMap/REPred2` to the exact pointwise `rel` statement, closes with `rw [toD1Code_rel_iff]` plus a two-line `constructor/rintro/exact` shuffling the `unpair_pair_fst/unpair_pair_snd` simplifications into place. **One wrinkle not anticipated by the plan:** `Exercise812d.lean` did not import `Definition72.lean` (only `Exercise812c/Definition71`, which happened to suffice for every earlier (d)(5) sub-part since none needed `IsComputableMap` itself, only `ComputablePresentation/ApproximableMap` machinery) — `IsComputableMap` was an unbound identifier until `import Scott1980.Neighborhood.Def` was added (one-line, file-wide fix). Zero sorry; lake build Scott1980 (3165 jobs) and lake env lean Exercise812d.lean both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning on `yPseqAtomIdx_eq_of_dichotomy` remains, unchanged). `#print axioms domainIsoCode812d_isComputableMap` gives $\subseteq \{\text{propxt}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section's established baseline.

Exercise 8.12(d)(5)(f)(iii): `toD0Code_rel_iff`

- **Mathematical Target:** `theorem toD0Code_rel_iff (m n : ℕ) : (ofIso (domainIsoCode812d ...).symm).rel (P1.X m) (P0.X n) ↔ ∃ k, P0.X n = P0.X (YPseqCode ... k) ∧ P1.X m ⊆ P1.X k`
- **Lean File:** `Exercise812d.lean` (new section `ToD0CodeRelIff`, appended after `DomainIsoCode812dIs`

- **Proof Notes:** matched the plan exactly, first try, no surprises — the exact mirror of (f)(i)’s `toD1Code_rel_iff` with $P_0/P_1, D_0/D_1, \text{toD1Code}/\text{toD0Code}, \text{XPseqCode}/\text{YPseqCode}$ swapped throughout: `show (∃ _ : D1.mem (P1.X m), (toD0Code ... (D1.principal (P1.mem_X m))) .mem (P0.X n)) ↔ _` (relying on `domainIsoCode812d.symm.toFun = domainIsoCode812d.invFun = toD0Code ...` holding definitionally, exactly as `Theorem88n.lean`’s `isoProj_rel_iff_incl` relies on the same fact for `domainIsoCode`), `simp only [toD0Code, mem_principal]`, then the same two-line constructor/`rintro`/exact shape as `toD1Code_rel_iff`. Zero sorry; lake build Scott1980 (3165 jobs) and lake env lean Exercise812d.lean both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning on `yPseqAtomIdx_eq_of_dichotomy` remains, unchanged). `#print axioms toD0Code_rel_iff` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(5)(f)(iv): `domainIsoCode812d_symm_isComputableMap`

- **Mathematical Target:** `theorem domainIsoCode812d_symm_isComputableMap : IsComputableMap P1 P0 (ofIso (domainIsoCode812d ...).symm)`
- **Lean File:** `Exercise812d.lean` (new section `DomainIsoCode812dSymmIsComputableMap`, appended after `ToD0CodeRelIff`)
- **Proof Notes:** matched the plan exactly, first try, no surprises — exact mirror of (f)(ii)’s `domainIsoCode812d_isComputableMap` via (f)(iii)’s `toD0Code_rel_iff`, swapping $P_0 \leftrightarrow P_1$ and $\text{XPseqCode} \leftrightarrow \text{YPseqCode}/\text{primrec_YPseqCode}$ throughout: `hA : RecDecidable (fun w => P0.X w.unpair.2.unpair.2 = P0.X (YPseqCode ... w.unpair.1))` via `P0.eq_computable.comp hg` (`hg` built from `primrec_YPseqCode`); `hB : RecDecidable (fun w => P1.X w.unpair.2.unpair.1 ⊆ P1.X w.unpair.1)` via `P1.incl_computable.comp hh`; `(hA.and hB).re.proj` closes the outer $\exists k$; final `REPred.of_iff` after a `show to unfold IsComputableMap P1 P0 (ofIso (domainIsoCode812d ...).symm)`, closed via `rw [toD0Code_rel_iff]` plus the same constructor/`rintro`/exact shuffle as (f)(ii). Zero sorry; lake build Scott1980 (3165 jobs) and lake env lean Exercise812d.lean both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning on `yPseqAtomIdx_eq_of_dichotomy` remains, unchanged). `#print axioms domainIsoCode812d_symm_isComputableMap` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline. **Completes 8.12(d)(5)(f) — hence 8.12(d)(5) in full.**

Exercise 8.12(d)(6)

- **Mathematical Target:** Final assembly: package into `EffectiveIso P0 P1`, completing the effective refinement of Exercise 8.12(c)
- **Lean File:** — (not yet started); umbrella — see sub-rows **8.12(d)(6)(a)–(c)** below
- **Proof Notes:** headline theorem (something like: given computable `splitX/splitY` satisfying `SplitSpec'` relative to P_0/P_1 , plus `hXcover/hYcover/hX0/hY0`, $D_0 \cong^D D_1$ from (c)(vii) upgrades to `EffectivelyIsomorphic P0 P1`). **Cross-reference finding from (d)(4)’s scoping (2026-07-04):** `toMap/invMap` should likely just be `ofIso domainIso812c/ofIso domainIso812c.symm` (`Theorem 2.7, Approximable.lean`), with `left_inv/right_inv` following from `toElementMap_ofIso + domainIso812c`’s own `left_inv/right_inv`, mirroring `Theorem88n.lean`’s `isoProj_comp_isoInj/isoInj_comp_isoProj` almost verbatim; the only genuinely new work is `toMap_computable/invMap_computable`, i.e. (d)(5). **Correction (2026-07-05, (d)(5)’s scoping):** `domainIso812c` specifically cannot be reused (see (d)(5)’s row, finding 1) — substitute a fresh `domainIsoCode812d` built on `atomPairG/XPseqCode/YPseqCode ((d)(5)(e))` for `domainIso812c` throughout this note;

the ofIso/toElementMap_ofIso/Theorem88n.lean-mirroring plan otherwise stands. **Further correction (2026-07-05, (e)’s scoping):** “computable splitX/splitY satisfying SplitSpec'” (this row’s opening clause) is very likely overstated — grep-confirmed that Exercise812d.lean’s XPseqCode/YPseqCode chain (which domainIsoCode812d is built on) never assumes SplitSpec'/hxSplit/hySplit, only IsComputableSplit; see (e)’s row, findings 1–2, for the full argument (and why a literal SplitSpec' for a Q.X-valued split would be inconsistent for U/V specifically, since neither presentation’s range ever includes literal $\emptyset$). Re-verify this once (d) (5) is actually executed; if confirmed, this row’s hypothesis list should drop SplitSpec' entirely. **Re-scoping investigation (2026-07-05, now that (d) (5) is complete), done before writing any code:**

1. **Correction to the “further correction” above: SplitSpec' (hxSplit/hySplit) is *not* droppable** — it is already a load-bearing hypothesis of (d) (5)’s own theorems, contradicting (e)’s finding 1. (e)’s finding 1 is about AtomPairCode/XPseqCode/YPseqCode *bare index formulas*, which indeed only cite IsComputableSplit directly. But grep-confirmed: hxSplit/hySplit (SplitSpec' D₁ splitX/SplitSpec' D₀ splitY) genuinely appear inside the proof terms of the (b) interleaving layer’s disjointness facts (e.g. xStepG_disjoint_of_ne hxSplit ... at Exercise812d.lean:4150,4162,4600,4631) — the “different atoms are disjoint” arguments up_mem/toD1Code/toD0Code/domainIsoCode812d all transitively depend on. Confirmed independently by Lean’s own linter.unusedSectionVars: every (d) (5) (f) theorem’s include hxSplit ... hySplit ... list was accepted with **zero** unused-variable warning on hxSplit/hySplit specifically (only hD₀nomin/hD₁nomin, in one unrelated pre-existing theorem, are ever flagged) — if hxSplit/hySplit were truly dead weight the same linter would have caught it, exactly as it did for hD₀nomin/hD₁nomin. **Net correction: this row’s hypothesis list is simply identical to (d) (5) (f)’s own include list** (P₀ P₁ hDiff0 hDiff1 splitX hSplitX splitY hSplitY hD₀pos hD₀diff hD₀nomin hxSplit hD₁pos hD₁diff hD₁nomin hySplit hD₀mne hD₁mne hUnion0 hUnion1 hX0 hY0) — no reduction, no addition, and (contra the previous note) no new “SplitSpec' relative to P₀/P₁” concept is needed; hxSplit : SplitSpec' D₁ splitX/hySplit : SplitSpec' D₀ splitY are literally the plain, already-included hypotheses. (e)’s own finding 1 stands unaffected for *its* actual question (whether a *concrete* U/V-side splitX/splitY can be built satisfying literal SplitSpec' — it cannot, for the stated Q.X-valued-output reason) — that is a question about *constructing* a witness, orthogonal to this row’s question of what hypotheses the *abstract* (d) (6) theorem needs to be *handed*.
2. **The assembly itself needs no new mathematical content beyond (d) (5)’s already-Pass lemmas** — confirmed by direct analogy with Theorem88n.lean’s isoProj_comp_isoInj/isoInj_comp_isoProj, which are *generic* facts about ofIso of any OrderIso and its .symm, needing nothing about the specific iso beyond its bare OrderIso structure. With e := domainIsoCode812d ... in hand: toMap := ofIso e, invMap := ofIso e.symm (ApproximableMap D₀ D₁/ApproximableMap D₁ D₀, Approximable.lean’s Theorem 2.7); toMap_computable/invMap_computable are *literally* (d) (5) (f)’s domainIsoCode812d_isComputableMap/domainIsoCode812d_isComputableMap (no further work); left_inv/right_inv (ApproximableMap-level, invMap.comp toMap = idMap D₀/toMap.comp invMap = idMap D₁) are ext_of_toElementMap reduced (via toElementMap_comp) to toElementMap_ofIso twice plus OrderIso.symm_apply_apply/OrderIso.apply_symm_apply (a bare Mathlib OrderIso fact) plus toElementMap_idMap — *exactly* isoProj_comp_isoInj/isoInj_comp_isoProj’s own four-line proof shape (Theorem88n.lean lines 59–75), substituting domainIsoCode812d for domainIsoCode P. **Crucially, this route needs *none***

of (d)(5)(e)’s `toD0Code_toD1Code/toD1Code_toD0Code` directly — those were needed to construct `domainIsoCode812d` itself (as `OrderIso`’s own `left_inv/right_inv` fields), and once `domainIsoCode812d : DomainIso D0 D1` exists as a bona fide `OrderIso`, the `ApproximableMap`-level mutual-inverse facts follow generically from `ofIso/OrderIso.symm_apply_apply` alone, with zero re-derivation.

3. **Once `left_inv/right_inv` and the two `_computable` facts are in hand, `effectiveIso812d : EffectiveIso P0 P1/effectivelyIsomorphic_812d : EffectivelyIsomorphic P0 P1` are one-where-block/one-line packaging, exactly mirroring (d)(5)(e)(iv)’s `domainIsoCode812d/isomorphic_812d` assembly pattern.**
- **Sub-part breakdown:** re-scoped into 3 sub-parts, (d)(6)(a)–(c) below, mirroring (d)(5)(e)’s (e)(ii)/(e)(iii)/(e)(iv) pattern (one standalone lemma per mutual-inverse direction, then a final assembly) rather than (d)(5)(f)’s per-direction-pairing (since here there is no analogous `rel_iff/_isComputableMap` split — the two `_computable` fields are direct citations, not new proofs): (d)(6)(a) `invMap_comp_toMap` (the `left_inv` content, mirroring `isoProj_comp_isoInj`); (d)(6)(b) `toMap_comp_invMap` (the `right_inv` content, mirroring `isoInj_comp_isoProj`, independent of (a)); (d)(6)(c) the full `effectiveIso812d/effectivelyIsomorphic_812d` assembly (depends on (a)/(b) plus (d)(5)(f)’s `domainIsoCode812d_isComputableMap/domainIsoCode812d_symm_isComputableMap`).

Exercise 8.12(d)(6)(a): `invMap_comp_toMap`, the `left_inv` content

- **Mathematical Target:** theorem `invMap_comp_toMap : (ofIso (domainIsoCode812d ...).symm).comp (ofIso (domainIsoCode812d ...)) = idMap D0`
- **Lean File:** `Exercise812d.lean` (new section `InvMapComp812d`, appended after `DomainIsoCode812dSym`)
- **Proof Notes:** matched the plan exactly, first try, no surprises — direct transcription of `Theorem88n.lean`’s `isoProj_comp_isoInj` at `e := domainIsoCode812d ...`: apply `ext_of_toElementMap`; intro `x`; rw `[toElementMap_comp]`; show `(ofIso e.symm).toElementMap ((ofIso e).toElementMap x) = _`; rw `[toElementMap_ofIso, toElementMap_ofIso, OrderIso.symm_apply_apply, toElementMap_idMap]`. No case split, no search, five lines; no unfolding of named `isoInj/isoProj` abbreviations needed (unlike `Theorem88n.lean`) since `ofIso (domainIsoCode812d ...).symm` are written out directly. Zero sorry; lake build Scott1980 (3165 jobs) and lake env lean `Exercise812d.lean` both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning on `yPseqAtomIdx_eq_of_dichotomy` remains, unchanged). `#print axioms invMap_comp_toMap` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(6)(b): `toMap_comp_invMap`, the `right_inv` content

- **Mathematical Target:** theorem `toMap_comp_invMap : (ofIso (domainIsoCode812d ...)).comp (ofIso (domainIsoCode812d ...).symm) = idMap D1`
- **Lean File:** `Exercise812d.lean` (new section `ToMapComp812d`, appended after `InvMapComp812d`)
- **Proof Notes:** matched the plan exactly, first try, no surprises — exact mirror of (a)’s `invMap_comp_toMap` (independent of it), direct transcription of `Theorem88n.lean`’s `isoInj_comp_isoProj`: same five-line shape as (a) with `e/e.symm` swapped and `OrderIso.apply_symm_apply` in place of `OrderIso.symm_apply_apply`. Zero sorry; lake build Scott1980 (3165 jobs) and lake env lean `Exercise812d.lean` both clean (only the pre-existing (b)(ii)-era `linter.unusedSectionVars` warning on `yPseqAtomIdx_eq_of_dichotomy` remains, unchanged). `#print axioms toMap_comp_invMap` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline.

Exercise 8.12(d)(6)(c): effectiveIso812d/effectivelyIsomorphic_812d, final assembly

- **Mathematical Target:** `def effectiveIso812d : EffectiveIso P0 P1 where toMap := ofIso (domainIsoCode812d ...); invMap := ofIso (domainIsoCode812d ...).symm; toMap_computable := domainIsoCode812d_isComputableMap ...; invMap_computable := domainIsoCode812d_symm_isComputableMap ...; left_inv := invMap_comp_toMap ...; right_inv := toMap_comp_invMap ...` and theorem `effectivelyIsomorphic_812d : EffectivelyIsomorphic P0 P1 := ⟨effectiveIso812d ...⟩` — completes 8.12(d)(6), hence 8.12(d) as a whole
- **Lean File:** — (not yet started)
- **Proof Notes:** matched the plan exactly — pure citation assembly, zero new mathematical content. `toMap/invMap/toMap_computable/invMap_computable/left_inv/right_inv` are all direct citations of (d)(5)(e)(iv)’s `domainIsoCode812d`, (d)(5)(f)’s `domainIsoCode812d_isComputableMap/domainIsoCode812d_symm_isComputableMap`, and (a)/(b)’s `invMap_comp_toMap/toMap_comp_invMap`; `effectivelyIsomorphic_812d` is a one-line `⟨effectiveIso812d ...⟩` packaging, exactly mirroring (d)(5)(e)(iv)’s `domainIsoCode812d/isomorphic_812d` assembly pattern (and `Exercise718.lean`’s own `iterIterEffectiveIso`). Two small pieces of infrastructure were needed (not proof content): `import Scott1980.Neighborhood.Exercise718` (new, since `EffectiveIso/EffectivelyIsomorphic` weren’t previously in scope), `open ... Exercise718` (they live in namespace `Scott1980.Neighborhood.Exercise718`), `noncomputable def` (since `domainIsoCode812d` is noncomputable), and — the one non-obvious wrinkle — `effectivelyIsomorphic_812d`’s `include` line had to list `hDiff0 hDiff1 hSplitX hSplitY` explicitly (Lean’s auto-bound `include` only picks up variables appearing in the *stated type*, not ones used solely in the proof term calling `effectiveIso812d`). Zero sorry; `lake build Scott1980` (3165 jobs) and `lake env lean Exercise812d.lean` both clean (only the pre-existing unrelated `linter.unusedSectionVars` warning remains). `#print axioms effectiveIso812d/effectivelyIsomorphic_812d` both give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching this section’s established baseline. **This completes 8.12(d)(6) — hence 8.12(d) as a whole.**

Exercise 8.12(e)

- **Mathematical Target:** Part 5 of 7 — U satisfies (c)/(d)’s extension property relative to V : build a concrete `splitX : Set Q → Set N → Set Q → Set N × Set N` with `IsComputableSplit UComputablePresentation VComputablePresentation splitX` (the literal input (d)’s `XPseqCode/YPseqCode/domainIsoCode812d` track needs).
- **Lean File:** — (not yet started); umbrella — see sub-rows 8.12(e)(a)–8.12(e)(d) below
- **Proof Notes:** Re-scoping investigation (2026-07-05), done before writing any code, tracing exactly how (d)’s `IsComputableSplit/SplitSpec'` structures get *used* by `Exercise812d.lean`’s actual code (not just their declared types):
 1. Correction to (d)(6)’s note below (flagged, needs re-verification): the concrete `splitX/splitY` this track needs almost certainly do *not* need to satisfy the classical `SplitSpec'` at all — only `IsComputableSplit`. Grep-confirmed: the `AtomPairCode/XPseqCode/YPseqCode` sections of `Exercise812d.lean` (which (d)(5)’s `domainIsoCode812d` is built on) take `hSplitX : IsComputableSplit P0 P1 splitX/hSplitY : IsComputableSplit P1 P0 splitY` as their *only* split-related hypotheses — `SplitSpec'/hxSplit/hySplit` never appear in that chain (they belong to a *different*, `SplitSpec'`-based `atomPairG`, used only by (c)’s fully classical,

non-effective machinery). Moreover a literal `SplitSpec' V splitX` for a $Q.X$ -valued `splitX` would be internally inconsistent: `posIdx_spec/negIdx_spec` force every output to equal some $Q.X\ k$, and `V.mem/U.mem` both bake in `Set.Nonempty (V.mem X := $\exists\ k\ m, X = \text{levelSet}\ k\ m \wedge X.\text{Nonempty}$, similarly U.mem), so $Q.X\ k$ is never literally $\emptyset$ — but SplitSpec' demands literal $\emptyset$ outputs in some genuine cases. So SplitSpec' and IsComputableSplit cannot both hold of the same $Q.X$ -valued split function; only IsComputableSplit is actually consumed downstream.`

2. **Tracing `xSubStep`'s body resolves *why* this is fine:** `newJunk := selectFn junk 1 directEmpty` then both indices are overwritten to the sentinel 0 whenever `newJunk = 1` (`selectFn newJunk 0 directIdx/selectFn newJunk 0 splitIdx`), where `directEmpty` is decided *purely from the prober side* via the already-generic `emptyInterDec/emptyDiffDec ((d) (2), Pass)`. So the split's chosen-branch index is only ever *retained* (not junk-masked) exactly when the prober-side direct refinement is already known nonempty — `IsComputableSplit`'s bare index-equation is the only obligation the code layer ever imposes; a “should be $\emptyset$ ” branch's *actual* index value is irrelevant once masked.
 3. **But a fully context-blind split (ignoring X_n/A entirely, e.g. always bisecting B by a fixed rule) is ruled out**, not merely unnecessary: `XPseqCode` always forces the “+” sub-bit, so a context-blind split's V -side values would form a single $\subseteq$ -chain (nested bisection depths) for *every* n — but U 's $\subseteq$ order is not a chain (two disjoint rational intervals are incomparable), so `XPseqCode` could never be order-reflecting against a chain-only image. Genuine X_n -dependence, via the prober's own deciders, is unavoidable.
 4. **The one piece of genuinely new combinatorics the exercise originally anticipated — a computable canonical bisection of a single V -neighbourhood into two disjoint (hence, since $V.\text{mem} \rightarrow \text{Nonempty}$, automatically nonempty) proper V -pieces — is exactly `V_no_minimal`'s proof (`Exercise812.lean`), which is *already fully constructive* (refine one level finer via `upsample`, peel off one witnessing bit, its twin guarantees the rest is nonempty).** Mirrors `SplitU.lean`'s existing `splitULeft/splitURight` for U almost exactly; just not yet extracted into `Nat.Primrec` form. This — not the $[1/3, 2/3]$ -density argument the exercise's original combinatorial framing (now superseded by (c)/(d)'s abstract back-and-forth) anticipated — is the actual new content (e) needs.
 5. **(f) (below) turns out to need *no* new bisection at all** — it reuses `SplitU.lean` (U 's own canonical midpoint bisection, already `Pass` from Theorem 8.8(b)) directly, confirming the old “(f) expected easier” intuition, for a sharper reason than originally guessed (not V 's coarseness, but that U 's own bisection already exists).
- **Sub-part breakdown:** 4 dependent sub-goals, (e) (a)–(d) below, strictly sequential. **Policy note (2026-07-05):** every sub-goal below is now stated as a genuine Lean declaration; “Pass” means it typechecks (zero `sorry` for theorems) — no more prose-only “scoping” rows without a corresponding Lean artifact.

Exercise 8.12(e)(a): the split's contract, as Lean declarations

- **Mathematical Target:** every sub-goal from here on must be a genuine Lean declaration (`def/structure/theorem`), not prose — “Pass” means it typechecks in Lean (with zero `sorry` for anything claiming to be a theorem). For (e) (a): fix the design for (d)'s split index functions concretely, as real `defs` (no proof obligations — those are (e) (c)'s job):

```

- structure ComputableBisection {W} (Q : ComputablePresentation W) where
  left right : ℕ → ℕ; left_primrec; right_primrec; disjoint : ∀ k, Q.X (left
  k) ∩ Q.X (right k) = ∅; union : ∀ k, Q.X (left k) ∪ Q.X (right k) = Q.X
  k; left_congr : ∀ k k', Q.X k = Q.X k' → Q.X (left k) = Q.X (left k');
  right_congr : ∀ k k', Q.X k = Q.X k' → Q.X (right k) = Q.X (right k')

- noncomputable def ComputableBisection.posIdxFromBisection (n m k : ℕ) :
  ℕ := selectFn (emptyInterDec P (Nat.pair n k)) m (selectFn (emptyDiffDec
  P hDiff (Nat.pair n k)) m (B.left m))

- noncomputable def ComputableBisection.negIdxFromBisection (n m k : ℕ) :
  ℕ := selectFn (emptyInterDec P (Nat.pair n k)) m (selectFn (emptyDiffDec
  P hDiff (Nat.pair n k)) m (B.right m))

```

- **Lean File:** Scott1980/Neighborhood/Exercise812e.lean (new file, wired into Scott1980.lean)
- **Proof Notes:** i.e. exactly one of the two “exactly one side empty” cases is genuinely correct (= B, matching SplitSpec’s own $\cup = B$ convention, hence collapsing posIdx/negIdx’s first two branches to the same value m) and the other is a harmless placeholder (masked once directEmpty forces junk upstream, per the (e) row’s findings 1–3); the “both nonempty” case is the one place (e)(b)’s real bisection (B.left/B.right) is used. **left_congr/right_congr** are a well-definedness field discovered while *writing this file (2026-07-05)*, absent from the original prose plan: ComputablePresentation.X is generally many-to-one, so a genuine classical split : Set $\alpha \rightarrow$ Set $\gamma \rightarrow$ Set $\alpha \rightarrow$ Set $\gamma \times$ Set γ (needed to even state IsComputableSplit in (e)(c)) requires left/right’s output sets to depend only on Q.X k as a set, not on which raw index represents it — else (e)(c)’s posIdx_spec/negIdx_spec (stated $\forall n m k$, not just for one fixed representative) would not be provable. Built, typechecks, zero sorry; axiom-audited: both defs depends on axioms: [Classical.choice] only (inherited from emptyInterDec/emptyDiffDec’s own use of Classical.choice-extracted existence witnesses, (d)(2) — same footprint as everywhere else in this file, not a new choice made here).

Exercise 8.12(e)(b): SplitV.lean — a computable canonical bisection for V

- **Mathematical Target:** mirror SplitU.lean for V: Nat.Primrec splitVLeft/splitVRight : $\mathbb{N} \rightarrow \mathbb{N}$ with

```

- theorem splitV_disjoint (n : ℕ) : VX (splitVLeft n) ∩ VX (splitVRight n)
  = ∅
- theorem splitV_union (n : ℕ) : VX (splitVLeft n) ∪ VX (splitVRight n) =
  VX n

```

(nonemptiness of both pieces is free from V.mem $\rightarrow$ Nonempty, unlike SplitU.lean’s own extra splitU_left_ne/splitU_right_ne properness lemmas, which nothing downstream here actually needs).

- **Lean File:** — (not yet started); new file Scott1980/Neighborhood/SplitV.lean, mirroring SplitU.lean’s structure; umbrella — see sub-rows 8.12(e)(b)(i)–(iv) below
- **Proof Notes:** **Re-scoping investigation (2026-07-05), done before writing any code.** Unlike most of (d)(6)’s sub-parts (pure mirrors of already-existing Theorem88n.lean machinery), this genuinely needs **new** infrastructure not present anywhere in the code-base yet: V_no_minimal’s classical proof (Exercise812.lean lines 223–274) picks its splitting bit ℓ_0 via levelSet_nonempty_iff.mp hne — a bare classical existential — and

`LevelSetPrimrec.lean`'s existing `bExistsFn` combinator only *decides* “does a witness exist” ($\{0,1\}$ -valued), never *produces* one; no “smallest set bit” finder exists yet. Likewise the construction's $M \sim 2^{\ell_0}$ step needs a primitive-recursive stand-in for `Mathlib's Nat.xor`, which `LevelSetPrimrec.lean`'s own header already flags as *not* `Nat.Primrec`-exposed (the reason `myUpsample` etc. had to be hand-built in the first place) — no such xor/bit-clear primitive exists yet either. Both are comparable in scope to `LevelSetPrimrec.lean`'s own `bExistsFn/myUpsample` blocks (each ~70–130 lines: definition, `Nat.Primrec` proof, and a correctness spec). Only once these two exist do `splitVLeft/splitVRight`'s definitions become mechanical compositions, and only then is `V_no_minimal's hInter/hUnion` transcription (comparable in shape to `SplitU.lean`'s own `UX_splitULeft/splitU_disjoint/splitU_union`, ~150 lines) meaningful to attempt.

- **Sub-part breakdown:** 4 sequential sub-goals, (e) (b) (i)–(iv) below, mirroring `SplitU.lean`'s own natural separation (search/arithmetic primitives $\rightarrow$ definitions $\rightarrow$ correctness).

Exercise 8.12(e)(b)(i): `myFirstBit` — the least-set-bit search combinator

- **Mathematical Target:** a new, generic (not V -specific), reusable `Nat.Primrec` combinator `myFirstBit` (`m N : ℕ`) : $\mathbb{N}$ returning the smallest $\ell < N$ with `m.testBit  $\ell$  = true`, built via the same bounded `Nat.rec`-fold idiom as `bExistsFn/bForallFn` (`Recursive.lean`), but threading the found index (not a $\{0,1\}$ flag) through the recursion — e.g. fold state `sentinel N` (meaning “not found yet”) updated to i the first time `myTestBit m i = 1` is seen, scanning $i = 0, 1, \dots, N-1$.

```

- theorem primrec_myFirstBit : Nat.Primrec (fun t => myFirstBit t.unpair.1
  t.unpair.2)
- theorem myFirstBit_lt {m N : ℕ} (h : ∃ ℓ < N, m.testBit ℓ = true) : myFirstBit
  m N < N
- theorem myFirstBit_testBit {m N : ℕ} (h : ∃ ℓ < N, m.testBit ℓ = true)
  : m.testBit (myFirstBit m N) = true

```

- **Lean File:** `Scott1980/Neighborhood/SplitV.lean` (new file, wired into `Scott1980.lean`)
- **Proof Notes:** matched the plan closely, one genuine gotcha hit and fixed. Definition: `myFirstBit m N := Nat.rec 0 (fun i ih => selectFn (isZero (i - ih)) (selectFn (myTestBit m i) i (i+1)) ih) N` — folds $i = 0, \dots, N-1$; invariant $ih \leq i$ throughout, with $ih < i$ meaning “already found” (carried forward unchanged) and $ih = i$ meaning “not found yet” (test bit i , becoming the new witness i if set, else the new sentinel $i+1$). Rather than `bExistsFn`'s three-lemma pattern, proved a single combined invariant by induction (`myFirstBit_spec`, a disjunction: either a genuine witness $< N$ with `testBit` true there and minimality below it, or the sentinel $= N$ with `testBit` false everywhere $< N$), then derived `myFirstBit_le/myFirstBit_lt/myFirstBit_testBit` from it directly — cleaner than chasing three separate inductions. Needed one unfolding equation lemma `myFirstBit_succ` (`rfl`, mirroring `LevelSetPrimrec.lean`'s `myUpsampleJointStep_eq`) for `rw` to fire in the induction step, since a direct `show`-based unfold (mirroring `bExistsFn`'s own succ-case proofs) hit a (deterministic) timeout at `whnf` — the underscore-heavy partial `show` target apparently made unification too expensive; a fully-written-out `rfl` lemma sidesteps it cleanly. **Real gotcha (the one substantively new thing here, not anticipated in the plan):** `primrec_myFirstBit's have htb := primrec_myTestBit.comp (hm.pair hi)`, ascribed directly via `:= (no .of_eq)`, also hit the same `whnf` timeout — unlike `bExistsFn`'s own `hGfn` (built as one flat combinator expression with no intermediate `Nat.pair/.unpair` round-trip needing non-`rfl` simp lemmas to close), composing through an explicit `hm.pair hi` before `re.unpair`-ing forces the elaborator to

try to unify `(Nat.pair a b).unpair.1/.2` against `a/b` by raw `whnf`, which loops, since that identity is only available as the *lemmas* `unpair_pair_fst/unpair_pair_snd`, not by `defeq/rfl`. Fixed by giving `htb` via `.of_eq (fun w => by simp only [unpair_pair_fst, unpair_pair_snd])` instead of a bare `:=` — after that, `primrec_myFirstBit` compiles in ~2s with the *default* heartbeat budget (no `set_option maxHeartbeats` bump needed once the real `defeq` trap was removed). Zero sorry; lake build Scott1980 (3166 jobs) and lake env lean SplitV.lean both clean, zero new warnings. `#print axioms` on all five declarations gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the project-wide baseline.

Exercise 8.12(e)(b)(ii): a computable “clear one bit” / xor-with-power-of-2 primitive

- **Mathematical Target:** a new `Nat.Primrec` realization of $m \mapsto m \text{ } \overset{\sim}{\sim}{\sim} 2^\ell$ (or, more simply, of “clear bit ℓ of m ”, sufficient here since (e)(b)(i)’s ℓ_0 is always already known set at the point of use) — call it `myClearBit` ($m \ell : \mathbb{N} : \mathbb{N}$ — with:
 - theorem `primrec_myClearBit : Nat.Primrec (fun t => myClearBit t.unpair.1 t.unpair.2)`
 - theorem `myClearBit_eq_xor {m ℓ : ℕ} (h : m.testBit ℓ = true) : myClearBit m ℓ = m \overset{\sim}{\sim}{\sim} 2^\ell` (or the corresponding direct `testBit`-level correctness spec, whichever is more convenient downstream)
- **Lean File:** `Scott1980/Neighborhood/SplitV.lean`
- **Proof Notes:** matched the plan closely: `myClearBit m ℓ := m - 2^\ell` (plain truncated subtraction), `primrec_myClearBit` immediate from `primrec_sub2/primrec_two_pow` via `.of_eq fun _ => rfl` (no `defeq` traps here — unlike (e)(b)(i), no `Nat.pair/.unpair` round-trip is involved). Mathlib has *no* usable `Nat.testBit_sub`-style lemma (confirmed by search), so `myClearBit_eq_xor` was hand-built from `Nat.testBit_two_pow_mul_add ((2^i*a+b).testBit j = if j < i then b.testBit j else a.testBit (j-i))`, given $b < 2^i$ via a “decompose m around the $2^{(\ell+1)}$ boundary” argument: `hqr : m % 2^{(\ell+1)} = 2^\ell + m % 2^\ell` (from `m.testBit ℓ = true` forcing $m \% 2^{(\ell+1)} \in [2^\ell, 2^{(\ell+1)})$), then a single-wraparound `Nat.mod_mod_of_dvd+omega` argument, mirroring `LevelSetPrimrec.lean`’s `private mod_eq_sub_of_le_of_lt_two_mul` gives `hclear : myClearBit m ℓ = 2^{(\ell+1)} * (m / 2^{(\ell+1)}) + m % 2^\ell` directly from `Nat.div_add_mod+omega`; then one `Nat.testBit_two_pow_mul_add` application plus `Nat.testBit_xor/Nat.testBit_two_pow` (Mathlib) and a 3-way `lt_trichotomy j ℓ` case split ($j < \ell$: both sides reduce to `m.testBit j` via `Nat.testBit_mod_two_pow`; $j = \ell$: both sides `false/true^^true`, using `h` directly; $j > \ell$: both sides `m.testBit j` via `Nat.testBit_div_two_pow`, $j-(\ell+1)+(\ell+1)=j$) closes `Nat.eq_of_testBit_eq`’s bit-for-bit goal. **Choice-discipline gotcha (real, not anticipated):** the very first sub-step (`hb : (m % 2^{(\ell+1)}).testBit ℓ = true`, proved via `rw [Nat.testBit_mod_two_pow, h]; simp`) silently pulled in `Classical.choice` — bisected via `#print axioms` on each have in isolation (`hbTest` alone showed `[propext, Classical.choice, Quot.sound]`, every sibling sub-lemma clean) down to that one bare `simp` call, which apparently resolves the residual `decide (ℓ < ℓ+1) && true = true` goal through a classical `Decidable` fallback rather than the concrete `Nat.decLt` instance. Fixed by replacing `simp` with an explicit `decide_eq_true_iff.mpr (Nat.lt_succ_self ℓ) + Bool.true_and` rewrite chain — `#print axioms` on both declarations now gives $\subseteq \{\text{propext}, \text{Quot.sound}\}$, choice-free (per this project’s choice-discipline rule, since this is pure `Nat/Bool` arithmetic, not a genuine existence-witness extraction). Zero sorry; lake build Scott1980 (3166 jobs) clean.

Exercise 8.12(e)(b)(iii): splitVLeft/splitVRight definitions and Nat.Primrec

- **Mathematical Target:** given (e)(b)(i)–(ii), the actual split, following `V_no_minimal`’s construction: with $(k, m) := \text{canonIdx } n \text{ (unpaired)}$, $\ell_0 := \text{myFirstBit } (\text{myUpsample } k \text{ (k+1) } m) \text{ (2}^{(k+1)}\text{)}$,
 - `def splitVLeft (n : ℕ) : ℕ := Nat.pair (k + 1) (2 ^ ℓ₀)`
 - `def splitVRight (n : ℕ) : ℕ := Nat.pair (k + 1) (myClearBit (myUpsample k (k+1) m) ℓ₀)`
 - `theorem primrec_splitVLeft : Nat.Primrec splitVLeft`
 - `theorem primrec_splitVRight : Nat.Primrec splitVRight`
- **Lean File:** `Scott1980/Neighborhood/SplitV.lean`
- **Proof Notes:** matched the plan exactly — mechanical composition, no new gotchas. Two intermediate defs factor out the shared sub-computation (mirroring `SplitU.lean`’s own `splitMidCode` intermediate): `splitVUpsampled n := myUpsample k (k+1) m (Scott’s M, for (k, m) := canonIdx n unpaired)` and `splitVBit n := myFirstBit (splitVUpsampled n) (2^(k+1))` (Scott’s ℓ_0 , found directly on the upsampled mask rather than drawn from a classical existential on m — noted in the section docstring as fine since `upsample` duplicates every set bit of m into a matching pair at level $k+1$, so any set bit of M has a genuine twin; making this precise is (e)(b)(iv)’s job). `splitVLeft n := Nat.pair (k+1) (2^ℓ₀)`, `splitVRight n := Nat.pair (k+1) (myClearBit (splitVUpsampled n) ℓ₀)`. All four `Nat.Primrec` proofs are routine compositions (`primrec_canonIdx/primrec_myUpsample/primrec_myFirstBit/primrec_myClearBit/primrec_two_pow/Nat.Primrec.pair`), each closed by `.of_eq + simp only [unpair_pair_fst, unpair_pair_snd]` or plain `rfl` where no `Nat.pair/.unpair` round-trip is involved — no `whnf` timeouts this time (unlike (e)(b)(i)), since every composition here pairs already-`Nat.Primrec` functions directly rather than re-threading through an intermediate `Nat.pair`. `#print axioms` on all four gives $\subseteq \{\text{propext, Classical.choice, Quot.sound}\}$ — confirmed via `#print axioms primrec_canonIdx` that this `Classical.choice` is inherited from `canonIdx` itself (its definition needs classical decidability of `levelSet-nonemptiness`), matching the project-wide baseline already established by (e)(a)/(e)(b)(i), not a fresh leak (unlike (e)(b)(ii)’s false alarm — re-checked accordingly). Zero sorry; lake build `Scott1980` (3166 jobs) clean.

Exercise 8.12(e)(b)(iv): correctness — VX_splitVLeft/VX_splitVRight, splitV_disjoint, splitV_union

- **Mathematical Target:** transcribe `V_no_minimal`’s `hInter/hUnion` computations to the `canonIdx/VX` code level:
 - `theorem VX_splitVLeft (n : ℕ) : VX (splitVLeft n) = levelSet (k+1) (2^ℓ₀)`
(i.e. = Y from `V_no_minimal`’s proof, at code-level indices)
 - `theorem VX_splitVRight (n : ℕ) : VX (splitVRight n) = levelSet (k+1) (myUpsample k (k+1) m ^^^ 2^ℓ₀)` (i.e. = Z)
 - `theorem splitV_disjoint (n : ℕ) : VX (splitVLeft n) ∩ VX (splitVRight n) = ∅`
 - `theorem splitV_union (n : ℕ) : VX (splitVLeft n) ∪ VX (splitVRight n) = VX n`
- **Lean File:** `Scott1980/Neighborhood/SplitV.lean`; completes (e)(b)

- **Proof Notes:** matched the plan, plus the one genuine addition flagged since (e) (b) (iii): the **twin-bit fact**, needed for `VX_splitVRight`’s nonemptiness (which `canonIdx_eq_self_of_nonempty` genuinely requires to fire, unlike `hInter/hUnion` themselves which never needed it in the classical proof). Built bottom-up: `splitV_mask_nonempty` (the upsampled mask `M` always has *some* set bit $< 2^{(k+1)}$, inherited from `canonIdx` `n` always presenting a non-empty `levelSet` via `VX_nonempty`, transported up one level via `levelSet_myUpsample`) feeds `myFirstBit_lt/myFirstBit_testBit` directly, giving `splitV_bit_lt/splitV_bit_testBit`. `splitV_twin_testBit` (`M.testBit` ($\ell_0 \sim 2^k$) = `true` given `M.testBit` ℓ_0 = `true`) is proved *without* any fresh `testBit`-level `myUpsample` lemma: reduce both ℓ_0 and its twin $\ell_0 \sim 2^k \bmod 2^k$ (`hmod`, a small `Nat.eq_of_testBit_eq` argument — xor-ing in 2^k only ever touches bit k , so both sides’ bits $< k$ agree and both sides’ bits $\geq k$ vanish under the mod), then bridge `m`-level membership (`levelSet k m`) back up to `M`’s level (`levelSet (k+1) M`) via `levelSet_myUpsample`, entirely at the Set-membership level (`mem_levelSet`) rather than raw arithmetic. `splitV_left_nonempty/splitV_right_nonempty` then package `Y/Z`’s nonemptiness (`(2^ℓ₀).testBit ℓ₀` = `true` trivially; for `Z`, needs `xor_two_pow_ne_self` : $a \sim 2^k \neq a$, a two-line `Nat.xor`-cancellation argument, to see 2^{ℓ_0} ’s bit is *off* at the twin position). `VX_splitVLeft/VX_splitVRight` are then `canonIdx_eq_self_of_nonempty` unfoldings exactly mirroring `SplitU.lean`’s own `UX_splitULeft/UX_splitURight` show-then-rw idiom; `splitV_disjoint/splitV_union` transcribe `V_no_minimal`’s `hInter/hUnion` (`Exercise812.lean` lines 242–261) essentially verbatim once stated at the same `levelSet (k+1)` _ level via the above. **One real omega gotcha, twice:** $(2:\mathbb{N})^k < 2^{(k+1)}$ from the equation $h2 : 2^{(k+1)} = 2 \cdot 2^k$ alone made `omega` fail with “No usable constraints found” — `omega` treats $2^k/2^{(k+1)}$ as opaque atoms, and $x < 2x$ needs $x > 0$ which the bare equation doesn’t supply (unlike (e) (b) (ii)’s analogous step, which happened to have an unrelated `hrlt` : $_ < 2^\ell$ already in context supplying positivity “for free” via `N`’s $a < b \rightarrow b > 0$); fixed both occurrences by adding an explicit `Nat.two_pow_pos` positivity have before the `omega` call. Zero sorry; lake build `Scott1980` (3166 jobs) clean. `#print axioms` on all ten new declarations gives $\subseteq \{\text{propxt}, \text{Classical.choice}, \text{Quot.sound}\}$, the expected project-wide baseline (inherited from `canonIdx`, confirmed no fresh leak).

Exercise 8.12(e)(c): generic decider+ bisection $\rightarrow$ IsComputableSplit construction

- **Mathematical Target:** a *generic*, reusable construction (shared by (e) (d) and (f) (a)), building the classical `split` and proving it satisfies `IsComputableSplit` against (e) (a)’s already-Pass `posIdxFromBisection/negIdxFromBisection` (`Exercise812e.lean`):
 - `noncomputable def splitFromBisection {P Q} (hpos : _.IsPositive) (hnomin : _.NoMinimal) (hdiff : IsComputableDiff P) (B : ComputableBisection Q) : Set $\alpha \rightarrow$ Set $\gamma \rightarrow$ Set $\alpha \rightarrow$ Set $\gamma \times$ Set γ , defined via Classical.choose inversion ($\exists n k m, A = P.X n \wedge Xn = P.X k \wedge B' = Q.X m$) plus (e) (a)’s same case split, landing on Q.X (posIdxFromBisection ...)/Q.X (negIdxFromBisection ...) — well-defined as a genuine function of the sets $A/Xn/B'$ (not just of one arbitrarily-chosen representative index) precisely because emptyInterDec/emptyDiffDec are already set-level-invariant (emptyInterDec_eq_one_iff et al., (d) (2)) and ComputableBisection.congr/right_congr ((e) (a)) make B.left/B.right set-level-invariant too`
 - theorem `isComputableSplit_ofBisection` : `IsComputableSplit P Q (splitFromBisection hpos hnomin hdiff B)`
- **Lean File:** — (not yet started); umbrella — see sub-rows **8.12(e)(c)(i)–(ii)** below
- **Proof Notes:** **Re-scoping investigation (2026-07-05), done before writing any code, tracing exactly what `posIdx_spec/negIdx_spec` need down to `posIdxFromBisection`’s

actual body.** Unlike (e)(b)(iii) (pure mechanical composition), this genuinely needs new well-definedness infrastructure first: `splitFromBisection` must be a function of *sets*, but its `Classical.choose`-based definition can return *any* valid witness (n' , k' , m') presenting the same sets as the caller's (n , k , m) — so `posIdx_spec/negIdx_spec` (stated for the literal triple $(P.X\ n, Q.X\ m, P.X\ k)$) need `Q.X (posIdxFromBisection ... n' m' k') = Q.X (posIdxFromBisection ... n m k)` whenever $P.X\ n = P.X\ n'$, $P.X\ k = P.X\ k'$, $Q.X\ m = Q.X\ m'$. Tracing this down to `posIdxFromBisection`'s body (`selectFn (emptyInterDec ...) m (selectFn (emptyDiffDec ...) m (B.left m))`), `Exercise812e.lean` needs, in order: (1) **decider congruence** — `emptyInterDec/emptyDiffDec` depend only on the *sets* $P.X\ n \cap P.X\ k / P.X\ n \setminus P.X\ k$, not the raw indices (not yet stated anywhere, though provable from the existing `emptyInterDec_eq_one_iff/emptyDiffDec_eq_one_iff` plus a “both sides $\{0,1\}$ -valued and agree on $= 1$ ” argument); (2) **a genuine hypothesis gap, found by tracing** (comparable to (e)(a)'s `left_congr/right_congr` discovery): `emptyDiffDec_eq_one_iff` needs `V.DiffClosed` (`Exercise812c.lean`) — a *separate* `Prop` from `IsComputableDiff P` — which this row's draft signature (`hpos, hnomin, hdiff : IsComputableDiff P`) does not list; (3) only once (1)–(2) exist can `posIdxFromBisection/negIdxFromBisection`'s own set-level congruence be proved, by matching the two deciders' shared $\{0,1\}$ branch value against `B.left_congr/right_congr`. Splitting into (e)(c)(i) (this new congruence infrastructure) then (e)(c)(ii) (the `Classical.choose` definition + assembly, mechanical given (i)), mirroring (e)(b)'s own “new infrastructure $\rightarrow$ assembly” separation.

- **Sub-part breakdown:** 2 sequential sub-goals, (e)(c)(i)–(ii) below.

Exercise 8.12(e)(c)(i): decider congruence and `posIdxFromBisection/negIdxFromBisection` well-definedness

- **Mathematical Target:** the “function of sets, not raw indices” infrastructure `posIdx_spec/negIdx_spec` will need:
 - theorem `emptyInterDec_congr` (`hpos : V.IsPositive`) (`hnomin : V.NoMinimal`) $\{n\ n'\ k\ k' : \mathbb{N}\}$ (`hn : P.X n = P.X n'`) (`hk : P.X k = P.X k'`) : `emptyInterDec P (Nat.pair n k) = emptyInterDec P (Nat.pair n' k')`
 - theorem `emptyDiffDec_congr` (`hdiffClosed : V.DiffClosed`) (`hnomin : V.NoMinimal`) $\{n\ n'\ k\ k' : \mathbb{N}\}$ (`hn : P.X n = P.X n'`) (`hk : P.X k = P.X k'`) : `emptyDiffDec P hDiff (Nat.pair n k) = emptyDiffDec P hDiff (Nat.pair n' k')` — note the new `hdiffClosed : V.DiffClosed` hypothesis, absent from (e)(c)'s draft signature (see this row's finding 2)
 - theorem `posIdxFromBisection_congr` (`hpos`) (`hnomin`) (`hdiffClosed`) $\{n\ n'\ k\ k'\ m\ m' : \mathbb{N}\}$ (`hn : P.X n = P.X n'`) (`hk : P.X k = P.X k'`) (`hm : Q.X m = Q.X m'`) : `Q.X (posIdxFromBisection P hDiff B n m k) = Q.X (posIdxFromBisection P hDiff B n' m' k')`
 - theorem `negIdxFromBisection_congr` — same shape, for `negIdxFromBisection`
- **Lean File:** `Scott1980/Neighborhood/Exercise812e.lean` (appended, inside namespace `ComputableBisection`)
- **Proof Notes:** matched the plan closely. `emptyInterDec_congr/emptyDiffDec_congr`: both sides ≤ 1 (`emptyInterDec_le_one/emptyDiffDec_le_one`, `Pass`), and `_eq_one_iff` ((d)(2), `Pass`) plus `hn/hk` (rewritten into one side's `_eq_one_iff`) gives an `Iff` between the two $= 1$ facts (`h1.trans h2.symm`); combined with both ≤ 1 bounds, a bare `omega` call closes the final equality directly (no manual $\{0,1\}$ case split needed)

— `omega` handles the Iff-of-equalities hypothesis natively). `posIdxFromBisection_congr/negIdxFromBisection_congr`: unfold both sides, `rw` via the two decider-congruence lemmas to align both sides on the *same* decider values (at `n'`, `k'`), then `omega`-derived `{0,1}` case split on each; **one real gotcha**: the naive `rw [h1, selectFn_zero]` idiom (used successfully elsewhere in the codebase for single-occurrence rewrites) silently rewrites *only the first* of the two occurrences of `selectFn 0 m (...)` / `selectFn 0 m' (...)` — since `rw` abstracts one specific instantiation, not the general pattern — leaving the goal in a broken half-rewritten state; fixed by switching to `simp only [h1, selectFn_zero]` (and the `= 1` variants), which correctly rewrites every matching instantiation. 3 of the 4 branches close on `hm` alone; only the “both deciders silent” branch needs `B.left_congr/right_congr`, exactly as anticipated. Zero sorry; lake build Scott1980 (3166 jobs) clean. `#print axioms` on all four new declarations gives $\subseteq$ `{propext, Classical.choice, Quot.sound}` (inherited from `emptyInterDec/emptyDiffDec`’s own `Classical.choose`-based definitions, no fresh leak).

Exercise 8.12(e)(c)(ii): `splitFromBisection` and `isComputableSplit_ofBisection`

- **Mathematical Target:** given (e)(c)(i), the actual classical split and its `IsComputableSplit` proof:

```

      - noncomputable def splitFromBisection {P Q} (hpos) (hnomin) (hdiffClosed
        : V.DiffClosed) (hdiff : IsComputableDiff P) (B : ComputableBisection Q)
        : Set  $\alpha$   $\rightarrow$  Set  $\gamma$   $\rightarrow$  Set  $\alpha$   $\rightarrow$  Set  $\gamma \times$  Set  $\gamma$ 
      - theorem isComputableSplit_ofBisection : IsComputableSplit P Q (splitFromBisection
        hpos hnomin hdiffClosed hdiff B)
      
```
- **Lean File:** `Scott1980/Neighborhood/Exercise812e.lean` (appended, inside namespace `ComputableBisection`); completes (e)(c)
- **Proof Notes:** matched the plan, plus one genuine deviation from the `arxiv.md` draft signature and one piece of new work the plan slightly understated. **Deviation:** `splitFromBisection` itself takes only `P`, `hDiff`, `B` (not `hpos/hnomin/hdiffClosed`) — those three hypotheses are needed only for *correctness* (`isComputableSplit_ofBisection`, below), never for the definition itself, mirroring how `posIdxFromBisection/negIdxFromBisection` are themselves already hypothesis-free to *define*; `isComputableSplit_ofBisection` takes them instead. **New work beyond the plan:** `IsComputableSplit`’s `posIdx_primrec/negIdx_primrec` fields demand the *joint* primitive-recursiveness of the index function as a single `Nat.Primrec` witness of the packed triple `t.unpair.1`, `t.unpair.2.unpair.1`, `t.unpair.2.unpair.2` (`IsComputableSplit`’s own coding convention) — `posIdxFromBisection/negIdxFromBisection` were previously only known primitive recursive *compositionally* (built from primitive-recursive pieces) but never packaged this way, so `primrec_posIdxFromBisection/primrec_negIdxFromBisection` needed proving fresh (mirroring `LevelSetPrimrec.lean`’s `primrec_myUpsample` triple-argument idiom): unpack `t`’s three projections, feed `Nat.pair n k` through `primrec_emptyInterDec/primrec_emptyDiffDec`, chain two `primrec_selectFn` applications, and close with `.of_eq fun _ => rfl` (the packed and curried forms are definitionally equal, no `unpair_pair` massaging needed since no `Nat.pair/unpair` round-trip occurs). `splitFromBisection A B' Xn` is a dite on $\exists n m k, A = P.X n \wedge B' = Q.X m \wedge Xn = P.X k$ (order chosen to match `posIdxFromBisection`’s own `(n, m, k)` argument order, simplifying the nested `Exists.choose/choose_spec` extraction versus the plan’s `(n, k, m)` ordering), landing on `(Q.X (posIdxFromBisection ... h.choose h.choose_spec.choose h.choose_spec.choose_spec.choose), ...)` when it holds, `(B', B')` (never read downstream) otherwise. `isComputableSplit_ofBisection` needed

a `noncomputable def` (not theorem) — `IsComputableSplit` is a data-carrying structure (its `posIdx/negIdx` fields are $\mathbb{N}$ -valued functions), not a `Prop`, so `theorem ... where` fails elaboration (“is not a proposition”); `posIdx_spec/negIdx_spec` then proceed exactly per plan: `unfold, dif_pos` at the trivial witness $\langle n, m, k, \text{rfl}, \text{rfl}, \text{rfl} \rangle$, obtain the triple-conjunction from `hex.choose_spec.choose_spec.choose_spec`, and close with `(posIdxFromBisection_congr/negIdxFromBisection_congr ...).symm`. Zero sorry; lake build Scott1980 (3166 jobs) clean. `#print axioms` on all four new declarations gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (inherited from `posIdxFromBisection/negIdxFromBisection`’s own `Classical.choose`-based deciders plus `splitFromBisection`’s own fresh `Classical.choose` on the presentation-triple existential, no unexpected leak).

Exercise 8.12(e)(d): instantiate for $U \leftrightarrow V$ — `splitX812e`, the exercise’s literal target

- **Mathematical Target:** `splitX812e := splitFromBisection UComputablePresentation (U'sIsComputableDiff) B812e`, where `B812e : ComputableBisection VComputablePresentation` packages a computable canonical bisection for V , and

— `theorem isComputableSplit_812e : IsComputableSplit UComputablePresentation VComputablePresentation splitX812e`, via `isComputableSplit_ofBisection` fed `U_isPositive/U_noMinimal/U's diff-closedness`

- **Lean File:** — (not yet started); umbrella — see sub-rows 8.12(e)(d)(i)–(iii) below
- **Proof Notes: Re-scoping investigation (2026-07-05), before writing any code, tracing what `ComputableBisection`’s `left_congr/right_congr` fields actually demand of (e)(b)’s `splitVLeft/splitVRight`.** Result: `left_congr/right_congr` are false for `splitVLeft/splitVRight` as currently defined — the “expected free... but must be checked” hope flagged back in (e)(a)’s own docstring turns out not to hold, and this is a genuine mathematical gap, not a bookkeeping one. **Concrete counterexample:** V ’s codes are highly non-canonical — a fixed set is presentable at *any* sufficiently fine level via repeated `myUpsample` (`canonIdx` never collapses across levels, only handling the “empty $\rightarrow$ master” case), and `splitVLeft`’s output is a full residue class *at the input’s own level*, not at any level-independent invariant. Take $X = \text{evens}$: presented at $(k, m) = (1, 1)$, `splitVLeft` returns $Y = \text{levelSet } 2 \ 1 = \{n \equiv 0 \pmod{4}\} = \{0, 4, 8, 12, \dots\}$; presented at $(k, m) = (2, 5)$ ($5 = \text{myUpsample } 1 \ 2 \ 1$, the *same set evens*, merely upsampled once), `splitVLeft` returns $Y' = \text{levelSet } 3 \ 1 = \{n \equiv 0 \pmod{8}\} = \{0, 8, 16, 24, \dots\}$. $Y \neq Y'$ (e.g. $4 \in Y \setminus \text{setminus } Y'$) despite both codes presenting the identical VX -set. The raw splitting *bit* ℓ_0 genuinely is presentation-invariant (it always equals $\min X$, since upsampling only ever adds duplicate copies at *higher* bit positions, never disturbing the least one) — the failure is entirely in the *level* $k+1$ used as the residue-class modulus, which is not intrinsic to the set X , only to the presentation. **Fix:** canonicalize to the *minimal* level at which a set is genuinely periodic before bisecting — intrinsic to the set, hence presentation-independent — rather than `canonIdx` n ’s raw (possibly non-minimal) level. This is a substantial new piece of mathematics (finding the true period of a mask, proving primitive-recursiveness, and — the crux — proving *uniqueness* of the minimal presentation), comparable in scope to all of (e)(b) combined, not a quick fix; deliberately **not** folded into `canonIdx/VX` themselves (which are already **Pass** and load-bearing for the rest of the codebase) — kept as new, separate infrastructure used only by the bisection construction.

- **Sub-part breakdown:** 3 sequential sub-goals, (e)(d)(i)–(iii) below.

Exercise 8.12(e)(d)(i): minimal-level canonicalization for V's codes

- **Mathematical Target:** a presentation-independent canonical $(\text{level}, \text{mask})$ pair for any $\text{levelSet } k \ m$:
 - `def isPeriodicMask (k j m : ℕ) : ℕ` ($\{0,1\}$ -valued) — decides whether $\text{levelSet } k \ m$ is also presentable at level $j \leq k$, via the canonical witness $\text{myModPow2 } m \ (2^j)$ (m 's own low bits)
 - `def minLevel (k m : ℕ) : ℕ` — the smallest $j \leq k$ with $\text{isPeriodicMask } k \ j \ m = 1$
 - `def minMask (k m : ℕ) : ℕ` := $\text{myModPow2 } m \ (2^{\text{minLevel } k \ m})$
 - `theorem primrec_minLevel/primrec_minMask : Nat.Primrec ...`
 - `theorem levelSet_minLevel (k m : ℕ) : levelSet (minLevel k m) (minMask k m) = levelSet k m`
 - `theorem minLevel_unique {k1 m1 k2 m2 : ℕ} (h : levelSet k1 m1 = levelSet k2 m2) : minLevel k1 m1 = minLevel k2 m2  $\wedge$  minMask k1 m1 = minMask k2 m2` — the crux fact that actually delivers `left_congr/right_congr` in (e)(d)(ii)
- **Lean File:** `Scott1980/Neighborhood/MinLevel.lean` (new file, imports only `LevelSetPrimrec.lean`)
- **Proof Notes:** landed close to the re-scoping plan, with one load-bearing correction and one genuine simplification found while working it out. **Correction:** the plan's periodicity modulus was off by an exponent — `levelSet k m` reads `m.testBit (n % 2k)`, so the *meaningful* truncation of a level- k mask is $\text{myModPow2 } m \ (2^k) = m \% 2^{(2^k)}$ (matching `myUpsample_lt`'s own $< 2^{(2^k')}$ bound), not $m \% 2^k$ as the draft assumed; every mask truncation below uses this corrected scale throughout. **Simplification:** rather than the drafted “bounded $\forall i < 2^k$ periodicity check” (an $O(2^k)$ -body decidable predicate needing its own new bounded-quantifier infrastructure) plus a $\max k_1 \ k_2$ /strong-induction uniqueness argument, `isPeriodicMask k j m` is instead an $O(1)$ formula — compare `myUpsample j k (myModPow2 m (2j))` (upsampling m 's own low bits back up) against `myModPow2 m (2k)` (m 's own bits at its home level), via the standard `isZero-of-two-sided-truncated-subtraction` equality decider (`Exercise724.lean`'s idiom) — reusing already-Pass `myUpsample/myModPow2` wholesale instead of building new quantifier machinery. Its defining correctness fact, `isPeriodicMask_iff : isPeriodicMask k j m = 1  $\leftrightarrow$  levelSet k m = levelSet j m` (for $j \leq k$), falls out of two already-Pass facts alone — `levelSet_myUpsample` and `levelSet_inj_of_lt` (`LevelSetPrimrec.lean`) — with no new induction. `minLevel/minMask` are the exact `myFirstBit` (`SplitV.lean`) bounded-`Nat.rec`-fold idiom transplanted verbatim (`test isPeriodicMask k i m` in place of `myTestBit m i`, base case $j = k$ always available via `isPeriodicMask_self`); `primrec_minLevel`'s only wrinkle versus `primrec_myFirstBit` is that the “fixed parameter” threaded through `Nat.Primrec.prec` is the *pair* `pair k m` rather than a single `m`, requiring one extra `unpair.1.unpair.1/unpair.1.unpair.2` layer throughout — otherwise identical. **The crux, `minLevel_unique`,** ended up *not* needing the drafted $\max k_1 \ k_2$ /strong-induction machinery at all — it reduces to one new elementary lemma, `levelSet_presentable_imp_self`: *if `levelSet k m` is presentable at some level $j \leq k$ via **any** witness mask m' at all, it is already presentable there via the canonical witness `myModPow2 m (2j)` built from m alone.* Proved by two direct specializations of `levelSet j m' = levelSet k m`'s `Set.ext_iff` unfolding — once at $n = i$ and once at $n = i \% 2^j$, for a fixed bit position $i < 2^k$ — which pin down `m.testBit i = m.testBit (i \% 2j)` by pure substitution, no induction whatsoever (the two specializations' $(i \% 2^k)/((i \% 2^j)\% 2^k)$ mod-arithmetic collapse to i and $i \% 2^j$ respectively via `Nat.mod_eq_of_lt`, then the

two equations chain directly). With this lemma in hand, `minLevel_eq/minMask_eq` are a short `by_contra`/trichotomy argument (two minimal witnesses of the same presentability predicate, one strictly below the other, contradicts the smaller one’s own minimality — mirroring `myFirstBit_spec`’s own “no smaller witness” clause) plus one final `levelSet_inj_of_lt` call for the mask. Zero sorry; lake build Scott1980 (2986 jobs for this file alone, 3167 for the whole project) clean. #print axioms on `minLevel_unique/minLevel_eq/minMask_eq/levelSet_minLevel/primrec_minLevel/primrec_minMask/isPeriodicMask_iff/levelSet_presentable_imp_self` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ throughout (the same inherited Nat-order/decidability footprint documented project-wide, no fresh leak — this file introduces no `Classical.choice/Exists.choose` of its own).

Exercise 8.12(e)(d)(ii): redefine `splitVLeft/splitVRight` via the minimal presentation; `left_congr/right_congr`

- **Mathematical Target:** given (e) (d) (i), route `SplitV.lean`’s pipeline through `minLevel/minMask` instead of `canonIdx n`’s raw level, and prove the two missing `ComputableBisection` fields:
 - redefined `splitVLeft/splitVRight` (same shape as (e)(b)(iii), but built from `(minLevel (canonIdx n).1 (canonIdx n).2, minMask ...)` in place of `(canonIdx n).1, (canonIdx n).2` directly)
 - re-derived `VX_splitVLeft/VX_splitVRight/splitV_disjoint/splitV_union` (expected light re-derivations — same shape as (e)(b)(iv), just fed the canonical presentation)
 - theorem `splitVLeft_congr (hn : VX n = VX n') : VX (splitVLeft n) = VX (splitVLeft n')` (and `splitVRight_congr`), from (e) (d) (i)’s `minLevel_unique` applied to `canonIdx n/canonIdx n'`
- **Lean File:** Scott1980/Neighborhood/SplitV.lean (revised in place — nothing downstream referenced `splitVLeft/splitVRight/VX_splitVLeft/VX_splitVRight/splitV_disjoint/splitV_union` yet, confirmed by grep, so no disruption)
- **Proof Notes:** matched the plan closely, one mechanical addition and one real tactic gotcha. New intermediate `splitVMinLevel n := minLevel (canonIdx n).unpair.1 (canonIdx n).unpair.2/splitVMinMask n := minMask (canonIdx n).unpair.1 (canonIdx n).unpair.2` (with `primrec_splitVMinLevel/primrec_splitVMinMask, levelSet_splitVMin : levelSet (splitVMinLevel n) (splitVMinMask n) = VX n`, and `splitVMin_congr : VX n = VX n' → splitVMinLevel n = splitVMinLevel n' ∧ splitVMinMask n = splitVMinMask n'` — the last a direct citation of `MinLevel.lean`’s `minLevel_unique`, coercing `VX n = VX n'` to the `levelSet _ _ = levelSet _ _` shape it expects via a `have h : ... := hn` ascription, which typechecks by unfolding `VX`’s definition, no `show/unfold` needed). Every occurrence of `(canonIdx n).unpair.1/.unpair.2` in `splitVUpsampled/splitVBit/splitVLeft/splitVRight` and all of (e)(b)(iv)’s correctness theorems (`splitV_mask_nonempty` through `splitV_union`) replaced by `splitVMinLevel n/splitVMinMask n` — genuinely light re-derivations exactly as anticipated, `splitV_mask_nonempty`’s only change a `rw [levelSet_splitVMin]` swapped in for the old direct `VX_nonempty n` citation, `splitV_union`’s `hML` likewise gaining one `rw [levelSet_myUpsample ...]`; exact `levelSet_splitVMin n` step in place of the old bare `unfold splitVUpsampled VX`; exact `levelSet_myUpsample ...` `splitVLeft_congr/splitVRight_congr` turned out *stronger* than drafted: rather than only the *output sets* agreeing, `splitVMin_congr` forces `splitVUpsampled/splitVBit` — and hence `splitVLeft/splitVRight` themselves — to be the *literally identical raw index* for any two codes presenting the same `VX`-set (`splitVLeft_eq_of_congr/splitVRight_eq_of_congr`, proved first, by three chained `rw`s through `splitVMin_congr`’s pair; `splitVLeft_`

`congr/splitVRight_congr` then downgrade via one more `rw`) — closing by `congrArg`, as the plan anticipated, but at the index level rather than merely the set level. **One real gotcha (not anticipated):** `splitV_union`’s final `congr 1` step timed out at `whnf` (200000 heartbeats) once the level argument became `splitVMinLevel n + 1` instead of `(canonIdx n).unpair.1 + 1` — `congr`’s unification apparently tries to `whnf`-compare the (syntactically identical, but no longer “obviously shallow”) level arguments on both sides, triggering the exact “`whnf` doesn’t respect `maxHeartbeats`” pitfall already documented in `HANDOFF.md` for other bounded-`Nat.rec`-fold definitions (`minLevel`, `myFirstBit`, `subsetBChar` et al.) — `splitVMinLevel`’s own body routes through one such fold. Fixed by replacing `congr 1` with the more surgical `apply congrArg (levelSet (splitVMinLevel n + 1))`, which fixes the first argument outright (no unification search) and reduces directly to the mask-equality goal — no `@[irreducible]` needed, unlike the `Recursive.lean`-era instances of this pitfall, since here the fix is purely tactic-level (avoid `congr`’s general-purpose unification path entirely rather than blocking unfolding). Zero sorry; lake build `Scott1980` (3167 jobs) and lake env lean `SplitV.lean` both clean, zero new warnings. `#print axioms` on all 14 new/revised declarations (`splitVMinLevel/splitVMinMask`, `splitVMinLevel/primrec_splitVMinMask/levelSet_splitVMin/splitVMin_congr/splitVLeft_eq_of_congr/splitVRight_eq_of_congr/splitVLeft_congr/splitVRight_congr/VX_splitVLeft/VX_splitVRight/splitV_disjoint/splitV_union`) gives $\subseteq \{\text{propxt}, \text{Classical.choice}, \text{Quot.sound}\}$ throughout (the `Classical.choice` inherited from `canonIdx`’s own use, confirmed no fresh leak — matches the project-wide baseline established by (e) (b)/(e) (d) (i)).

Exercise 8.12(e)(d)(iii): package as `ComputableBisection`; instantiate for $U \leftrightarrow V$

- **Mathematical Target:** the exercise’s literal target, given (e) (d) (i)–(ii):
 - `def B812e : ComputableBisection VComputablePresentation` (from redefined `splitVLeft/splitV_disjoint/splitV_union`, `splitVLeft_congr/splitVRight_congr`)
 - `def splitX812e := splitFromBisection UComputablePresentation (U'sIsComputableDiff) B812e`
 - `theorem isComputableSplit_812e : IsComputableSplit UComputablePresentation VComputablePresentation splitX812e`
- **Lean File:** `Scott1980/Neighborhood/Exercise812eD.lean` (new file, wired into `Scott1980.lean`)
- **Proof Notes:** `B812e/splitX812e/isComputableSplit_812e` themselves matched the plan exactly — mechanical field-by-field assembly and two one-line instantiations, no surprises. **One real gap found while assembling, not anticipated by the scoping pass:** the plan’s parenthetical “(U’s `IsComputableDiff`)” assumed such an instance already existed — `grep`-confirmed it did not; `IsComputableDiff` (`Exercise812d.lean`, (d) (3) (a)) had never been instantiated for `U` or `V`. Building it turned out genuinely mechanical (not a new mathematical gap like (e) (d) (i)/(ii)’s), since `IntervalPrimrec.lean` already supplies every raw piece unconditionally: `diffCode/primrec_diffCode` (code-level set difference) and `presentedIntervals_decodeQPairList_diffCode` (its correctness — unconditional, no emptiness case split needed, unlike `combineCode`’s consistency side). `Udiff n m := diffCode (canonCode n) (canonCode m)` plus `Udiff_primrec/Udiff_eq_diff/U_diff_iff_nonempty/Udiff_spec/U_diff_computable` are a direct structural mirror of `UComputablePresentation.lean`’s own `Uinter/Uinter_primrec/Uinter_spec/U_cons_computable`, substituting `diffCode` for `combineCode` and `U_diff_mem` (`Exercise812c.lean`, already Pass) for `U_isPositive` as the “always mem-or- $\emptyset$ ” fact driving the “consistency $\equiv$ non-emptiness” decidability reduction (`U_diff_iff_nonempty`, mirroring `U_cons_iff_`

nonempty_inter). U_isComputableDiff then packages the four pieces directly. **One mechanical gotcha, same as (e)(c)(ii)’s:** isComputableSplit_812e needed noncomputable def, not theorem — IsComputableSplit is a data-carrying structure (posIdx/negIdx fields are $\mathbb{N}$ -valued functions), so theorem ... := fails elaboration (“is not a proposition”), exactly as documented for isComputableSplit_ofBisection itself. New file Exercise812eD.lean (not appended to Exercise812e.lean, to avoid pulling SplitV.lean/UComputable into that more foundational file). Zero sorry; lake build Scott1980 (3168 jobs) clean, zero new lints. #print axioms on all 10 new declarations (Udiff/Udiff_primrec/Udiff_eq_diff/U_diff_iff_nonempty/Udiff_spec/U_diff_computable/U_isComputableDiff_812e) gives $\subseteq \{\text{propext, Classical.choice, Quot.sound}\}$ throughout (Udiff itself is fully choice-free data; the Classical.choice elsewhere is inherited from U’s own cons_computable/canonCode machinery and splitFromBisection’s Classical.choose, matching the project-wide baseline, no fresh leak). **This completes 8.12(e) in full** — all of (a)–(d) are now Pass.

Exercise 8.12(f)

- **Mathematical Target:** Part 6 of 7 — V satisfies (c)/(d)’s extension property relative to U: build a concrete $\text{splitY} : \text{Set } \mathbb{N} \rightarrow \text{Set } \mathbb{Q} \rightarrow \text{Set } \mathbb{N} \rightarrow \text{Set } \mathbb{Q} \times \text{Set } \mathbb{Q}$ with $\text{IsComputableSplit } \text{VComputablePresentation } \text{UComputablePresentation } \text{splitY}$.
- **Lean File:** Scott1980/Neighborhood/Exercise812f.lean (new; also Scott1980/Neighborhood/UBisection2.lean and Scott1980/Neighborhood/VDiff.lean, prerequisites — see below)
- **Proof Notes:** The planned “single one-line instantiation” *was* ultimately a one-liner ($\text{splitX812f}/\text{isComputableSplit_812f}$, directly mirroring Exercise812eD.lean’s $\text{splitX812e}/\text{isComputableSplit_812e}$ with prober/target roles swapped), but **both of the plan’s flagged risks materialized as genuine gaps, not “plausibly free”**: (1) SplitU.lean’s $\text{splitULeft}/\text{splitURight}$ genuinely **fail** $\text{left_congr}/\text{right_congr}$ — canonCode clips/filters but never *merges* overlapping/adjacent intervals, so e.g. $[(0,1)]$ and $[(0,1/2),(1/2,1)]$ both canonically present U.master but have different first-pair midpoints ($1/2$ vs. $1/4$). Fixed with a new UBisection2.lean (does not touch SplitU.lean, kept as-is for 8.8(b)): split at the midpoint of the presented set’s *intrinsic* (min, max) — $\min X = \min_i p_{i.1}$ (attained, every Ico left-closed) and $\sup X = \max_i p_{i.2}$ (approached arbitrarily closely, listMaxSnd_tight) are genuine invariants of the set itself, not of its presentation, so splitting at their midpoint is automatically presentation-independent — no interval-merging machinery needed (lighter than MinLevel.lean’s analogous (e)(d) fix for V). listMinFst/listMaxSnd (list-level, direct List.foldl induction) mirrored at the code level (listMinFstCode/listMaxSndCode) via Recursive.lean’s foldCode folding ratMinCode/ratMaxCode; splitU2Left/splitU2Right reuse SplitU.lean’s clipLtListCode/clipGeListCode unchanged; splitU2Left_congr/splitU2Right_congr follow from listMinFst_congr/listMaxSnd_congr (antisymmetry/contradiction against _mem_presentedIntervals/_lower_bound/_upper_bound/_tight, mirroring MinLevel.lean’s minLevel_unique shape). Packaged as UBisection2 : ComputableBisection UComputablePresentation. (2) V’s IsComputableDiff instance had indeed never been built — new VDiff.lean mirrors LevelSetPrimrec.lean’s Vinter exactly, substituting Exercise812c.lean’s levelSet_diff (a ^^^ (a &&& b) via testBit_xor_and_self) for levelSet_myInter; the one new primitive needed, a choice-free bitwise XOR myXor (mirrors myLand/myLor bit-for-bit), composed as myAndNot a b := myXor a (myLand a b) — no new arithmetic identity beyond myXor_eq_xor/myLand_eq_land. V_isComputableDiff : IsComputableDiff VComputablePresentation packages Vdiff/Vdiff_primrec/Vdiff_spec/V_diff_computable. With both gaps closed:

– UBisection2 : ComputableBisection UComputablePresentation (fixed bisection,

```

left := splitU2Left, right := splitU2Right, left_congr/right_congr now genuinely proved)
- splitX812f := ComputableBisection.splitFromBisection VComputablePresentation
  V_isComputableDiff UBisection2
- isComputableSplit_812f := ComputableBisection.isComputableSplit_ofBisection
  VComputablePresentation V_isComputableDiff UBisection2 V_isPositive V_
  noMinimal V_diffClosed

```

Exercise 8.12(g)

- **Mathematical Target:** Part 7 of 7 — assembly: apply (c)/(d)’s general lemma to the concrete U, V using (e)/(f)’s extension-property proofs to conclude $U \cong^D V$ effectively, closing out Exercise 8.12
- **Lean File:** Scott1980/Neighborhood/Exercise812g1a.lean, Exercise812g1b.lean, Exercise812g2.lean, Exercise812g4.lean (plus Exercise812d.lean/Exercise812e.lean/Exercise812f.lean for (g) (3)’s split-contract repair); umbrella — see sub-rows **8.12(g)(1)–(4)**, all now Pass
- **Proof Notes: Scoping investigation (2026-07-06), then executed in full across three follow-up sessions.** The original “no new mathematical content, pure instantiation” guess (like the analogous guess for (f) that turned out wrong twice) was **also wrong here on first pass:** `effectiveIso812d` (Exercise812d.lean’s actual final-assembly theorem) takes a longer hypothesis list than (c)/(d)’s own headline lemmas alone — $P_0 \ P_1 \ hDiff0 \ hDiff1 \ splitX \ hSplitX \ splitY \ hSplitY \ hD_0pos \ hD_0diff \ hD_0nomin \ hxSplit \ hD_1pos \ hD_1diff \ hD_1nomin \ hySplit \ hD_0mne \ hD_1mne \ hUnion0 \ hUnion1 \ hX0 \ hY0$ — needing four genuinely new facts beyond (c)–(f)’s own: $hxSplit/hySplit : SplitSpec'$ (a *different*, Prop-only set-level splitting contract from `IsComputableSplit`, never proved for either concrete split — (g) (3), the hard part, below), $hUnion0/hUnion1 : IsComputableUnion$ (never instantiated for either U/V — (g) (2)), and $hX0/hY0 : UX \ 0 = U.master/VX \ 0 = V.master$ ((g) (1)). All four have since been built: (g) (1)/(g) (2) were genuinely mechanical, as scoped; (g) (3) was **not** — the original *unconditional* `IsComputableSplit.posIdx_spec/negIdx_spec` contract turned out to be **jointly unsatisfiable** with `SplitSpec'` (any split that always presents its output as some $Q.X \ j$, never literally $\emptyset$, cannot match `SplitSpec'`’s $A \cap Xn = \emptyset \leftrightarrow .1 = \emptyset$ when $Q.X \ j$ is never $\emptyset$, true for both U/V), requiring `IsComputableSplit` itself to be weakened (conditional `_spec` fields) and `splitFromBisection` redesigned (three-way branch: two decider-fires branches give the literal $\emptyset/B'$ pair directly, only the “neither fires” branch uses the genuine bisection) before the concrete instances could be proved — see (g) (3)’s row for the full repair. (g) (4)’s final instantiation then went through with zero surprises once (g) (1)–(g) (3) were in place.

Exercise 8.12(g)(1)

- **Mathematical Target:** The small assembly prerequisites `effectiveIso812d` needs beyond (c)/(d)/(e)/(f)’s own headline facts: $U.master.Nonempty/V.master.Nonempty$ (hD_0mne/hD_1mne) and $UX \ 0 = U.master/VX \ 0 = V.master$ ($hX0/hY0$)
- **Lean File:** — (not yet started); umbrella — see sub-rows **8.12(g)(1)(a)–(b)** below for the by-system breakdown
- **Proof Notes: Re-scoped 2026-07-06, verified directly against source (not guesswork) before writing any code.** All four facts are confirmed short/mechanical with

zero new mathematical content, but they decompose along **two genuinely independent chains, one per system** (U’s rational-interval representation vs. V’s bitmask representation — the same axis (e)/(f) were already split on), so tracked as two sub-rows rather than one bundled item: **8.12(g)(1)(a)** (U-side: `U.master.Nonempty + UX 0 = U.master`) and **8.12(g)(1)(b)** (V-side: `V.master.Nonempty + VX 0 = V.master`). Both `master.Nonempty` facts turn out to be *more* trivial than the original guess (no `NoMinimal` needed at all — `U.master = Set.Ico 0 1/V.master = Set.univ` are directly nonempty). Both `hX0/hY0` are confirmed real (the fallback-on-0 guess was correct) via explicit unfolding, one exact short lemma-chain each — see sub-rows for the chains.

Exercise 8.12(g)(1)(a)

- **Mathematical Target:** U-side of (g)(1): `U.master.Nonempty (hD0mne)` and `UX 0 = U.master (hX0)`
- **Lean File:** `Scott1980/Neighborhood/Exercise812g1a.lean` (new file, wired into `Scott1980.lean`)
- **Proof Notes:** Matched the scoping plan exactly, no surprises. `U_master_nonempty : U.master.Nonempty := ⟨0, by norm_num [U]⟩` (needs `[U]` in the `norm_num` simp-set to unfold the structure projection `U.master` down to `Set.Ico 0 1` — plain `norm_num` alone leaves `0 ∈ U.master` unsolved, the one real gotcha, found immediately by `lake build`, not anticipated in the scoping note). `UX_zero : UX 0 = U.master`: `UX_eq` rewrites to `presentedIntervals (canonList (decodeQPairList 0))`; `decodeQPairList 0 = []` (unfold `decodeQPairList`; `rw [decodeList_zero]`); `canonList_eq_of_filter_eq_nil` (by `simp`) collapses it to `presentedIntervals [(0,1)]`; `presentedIntervals_cons/presentedIntervals_nil/Set.union_empty` plus a final `rfl` (`Set.Ico 0 1` unfolds definitionally to `U.master`) close it — the exact four-lemma chain planned. Zero sorry; `lake build Scott1980` (3172 jobs) clean, zero new lints. `#print axioms U_master_nonempty/UX_zero` both give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching `Definition87.lean`’s documented upstream $\mathbb{Q}$ -order-taint baseline (no fresh leak).

Exercise 8.12(g)(1)(b)

- **Mathematical Target:** V-side of (g)(1): `V.master.Nonempty (hD1mne)` and `VX 0 = V.master (hY0)`
- **Lean File:** `Scott1980/Neighborhood/Exercise812g1b.lean` (new file, wired into `Scott1980.lean`)
- **Proof Notes:** Matched the scoping plan exactly, no surprises (unlike (g)(1)(a)’s one `norm_num [U]` gotcha, this side had none). `V_master_nonempty : V.master.Nonempty := Set.univ_nonempty (V.master = Set.univ` is definitional, no unfolding lemma needed at all). `levelSet_zero_zero : levelSet 0 0 = ∅` is a new one-line reusable fact (`ext n; simp [levelSet, Nat.zero_testBit]` — `Nat.zero_testBit` was already in the code-base’s vocabulary, used elsewhere in `Exercise723.lean/Example78.lean`). `VX_zero : VX 0 = V.master`: `Nat.unpair_zero (Nat.unpair 0 = (0,0)`, a pre-existing `Mathlib/Recursive.lean` fact) plus `levelSet_zero_zero` feed directly into `canonIdx_eq_master_of_empty` to get `canonIdx 0 = VmasterIdx`; rewriting `VX 0` to `VX (canonIdx 0)` via $\leftarrow$ `VX_canonIdx 0` and substituting closes it with the already-`Pass VX_VmasterIdx` — exactly the planned “compose one step further” chain, no new lemma needed at the `VX/V.master` level beyond `levelSet_zero_zero`. Zero sorry; `lake build Scott1980` (3173 jobs) clean, zero new lints. `#print axioms V_master_nonempty/VX_zero` both give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the project-wide baseline (no fresh leak). **This completes Exercise 8.12(g)(1) in full** — both (a) and (b) are now `Pass`.

Exercise 8.12(g)(2)

- **Mathematical Target:** `IsComputableUnion` `UComputablePresentation` and `IsComputableUnion` `VComputablePresentation` (Exercise812d.lean’s (d) (3) (a)-shaped structure for $\cup$ instead of $\setminus$) — never instantiated for either concrete system
- **Lean File:** `Scott1980/Neighborhood/Exercise812g2.lean` (new file, wired into `Scott1980.lean`)
- **Proof Notes:** Matched the scoping plan closely — indeed the easiest of the four sub-parts, purely mechanical, no new mathematical content — with three small execution-time gotchas, none a real gap: (1) a naming clash — `Definition87.lean` already has a `U_union_mem` (the $= \emptyset \vee \text{mem}$ -dichotomy lemma for raw `U.mem`, unrelated), so the new unconditional UX-level fact is named `U_union_UX_mem` instead. (2) `Union_eq_union` (presentedIntervals (decodeQPairList (Uunion n m)) = $UX\ n \cup UX\ m$, via `presentedIntervals_append + decodeQPairList_appendListCode`) needed an explicit trailing `rfl`, not automatic. (3) **The one genuine near-miss:** an initial `U_union_exists` := $\langle \text{Uunion } n\ m, \text{Union_eq_union } n\ m \rangle$ caused a `whnf` deterministic timeout, because `UX (Uunion n m)` unfolds to the *canonicalized* `presentedIntervals (decodeQPairList (canonCode (Uunion n m)))`, one `canonCode` layer more than `Union_eq_union`’s raw (uncanonicalized) statement — conflating the two sent the elaborator into a very expensive unification search rather than a clean type error. Fixed by deriving `U_union_exists` independently via `U_surj_UX (U_union_UX_mem n m)` (mirroring `U_diff_iff_nonempty`’s own use of `U_surj_UX`) instead of routing through `Union/Uunion_eq_union` at all. U-side (`Uunion := appendListCode (canonCode n) (canonCode m)`, mirroring `Udiff`, substituting the pre-existing `appendListCode/primrec_appendListCode/appendListCode_eq` (`Recursive.lean`) for `diffCode`) and V-side (`Vunion/VunionRaw`, mirroring `Vinter/VinterRaw` verbatim, substituting the pre-existing `myLor/primrec_myLor/myLor_eq_lor` (`Recursive.lean`, already used by `Example78.lean`’s PN) for `myLand`, and a new `levelSet_myUnion` — the computable version of `Exercise812.lean`’s inlined `V_union_mem` identity — for `levelSet_myInter`) both confirm the scoping note’s prediction: **unconditional**, no “-or- $\emptyset$ ” case split anywhere, `unionIdx_spec`’s hypothesis literally unused in both `Uunion_spec/Vunion_spec`, and `union_computable` for both reduces to the trivial always-1 decider ($\langle \text{fun } _ \Rightarrow 1, \text{Nat.Primrec.const } 1, \text{fun } t \Rightarrow \text{iff_of_true } (\dots_exists \dots) \text{ rfl} \rangle$). Zero sorry; lake build `Scott1980` (3174 jobs) clean, zero new lints. `#print axioms U_isComputableUnion/V_isComputableUnion` both give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the project-wide baseline (no fresh leak).

Exercise 8.12(g)(3)

- **Mathematical Target:** `SplitSpec' V splitX812e` and `SplitSpec' U splitX812f` — the Prop-only, set-level splitting contract that (c)’s abstract `xStep/yStep/DomainIso` machinery (and hence (d)’s `effectiveIso812d`) actually consumes, for the two concrete splits built in (e)/(f)
- **Lean File:** `Exercise812d.lean` (`IsComputableSplit` redesign), `Exercise812e.lean` (`splitFromBisection` redesign + `splitFromBisection_isSplitSpec`), `Exercise812eD.lean` (`hxSplit812e`), `Exercise812f.lean` (`hySplit812f`) — **complete in full as of 2026-07-06 (part 3)**
- **Proof Notes:** **2026-07-06 (part 1): confirmed `SplitSpec' V splitX812e` FALSE as originally architected** — full argument below, superseded by part 2’s repair. **2026-07-06 (part 2): repaired the root cause identified in part 1**, exactly option (a) flagged at the end of part 1 (`IsComputableSplit.posIdx_spec/negIdx_spec` weakened to be conditional on non-emptiness, then the change propagated through every

consumer). This unblocks the *design* — `IsComputableSplit` and `SplitSpec'` are no longer structurally incompatible — but does **not** by itself produce a `SplitSpec'`-satisfying concrete split: `splitFromBisection` (`Exercise812e.lean`) still unconditionally returns `Q.X m` (never literally $\emptyset$) on both branches whenever a decider fires, so `SplitSpec' V splitX812e` is *still* not proved (nor provable as `splitFromBisection` is currently defined) — that half of (g)(3) remains open, now as a tractable, unblocked task rather than an impossible one. Part 1’s original argument, for the record:

1. `splitX812e := ComputableBisection.splitFromBisection UComputablePresentation U_isComputableDiff B812e`. Its two outputs were, by `IsComputableSplit`’s *original, unconditional* contract (`posIdx_spec/negIdx_spec`, `Exercise812d.lean (d)(2)`), *always* literally `Q.X (posIdxFromBisection ...)` / `Q.X (negIdxFromBisection ...)` where `Q := VComputablePresentation`.
2. `Q.X j` is **never** $\emptyset$, for any `j` — `Q.mem_X :  $\forall n, V.mem (Q.X n)$  and  $V.mem X := \exists k\ m, X = \text{levelSet } k\ m \wedge X.\text{Nonempty}$` (`Exercise812.lean` line 199) structurally *requires* nonempty; the mirror fact holds for `U/UComputablePresentation (U.mem X := ...  $\wedge X.\text{Nonempty} \wedge \dots$ , Definition87.lean line 96)`.
3. `posIdxFromBisection/negIdxFromBisection` (`Exercise812e.lean`) *by design* both evaluate to `m` (i.e. literally `B` itself, not $\emptyset$) whenever **either** `emptyInterDec/emptyDiffDec` fires.
4. Concretely: whenever `A  $\cap$  Xn =  $\emptyset$` while `B  $\neq \emptyset$` (routine and unavoidable), `SplitSpec'` demands `(splitX812e A B Xn).1 =  $\emptyset$` , but by (1)–(3) the actual value was `Q.X m = B  $\neq \emptyset$` . A genuine contradiction under the *original* unconditional `posIdx_spec/negIdx_spec`.
5. Not sidesteppable by supplying a *different* already-available split: `effectiveIso812d/domainIsoCoo` (`Exercise812d.lean (d)(6)`) bind `hxSplit : SplitSpec' D1 splitX` to the **same** `splitX` as `hSplitX : IsComputableSplit P0 P1 splitX`, and the choice-based `splitChoice'` (`Exercise812c.lean`) satisfies `SplitSpec'` but cannot satisfy `IsComputableSplit` (not primitive recursive).
6. **The repair (part 2):** weakened `IsComputableSplit.posIdx_spec/negIdx_spec` from unconditional `(split ...).1 = Q.X (posIdx ...)` to conditional `(split ...).1  $\neq \emptyset \rightarrow$  (split ...).1 = Q.X (posIdx ...)` (symmetrically for `negIdx_spec/.2`) — exactly the fix sketched in part 1’s root-cause note. Propagated through `Exercise812d.lean`: `posIdx_mem/negIdx_mem` corollaries gained the same `hne` hypothesis; `xSubStep_correct/ySubStep_correct ((d)(3)(b))` now derive the needed non-emptiness from `SplitSpec'`’s own “empty iff empty” conjunct plus `emptyInterDec_eq_one_iff/emptyDiffDec_eq_one_iff` (needing `atomPairG_invariant`-style `hAB/hBmem` preconditions threaded in from every call site) before invoking `posIdx_spec/negIdx_spec`, rather than getting the equality for free; the same pattern (derive `$\neq \emptyset$` from the junk-flag being 0 via `selectFn_one_eq_zero_iff` + the relevant `*Dec_eq_one_iff`, then feed `SplitSpec'`’s `.2.2.1/.2.2.2.1` conjunct) recurs through `atomPairCodeState_correct`, `xPseqAtomIdx_subset_atomPairIdx1`, `xPseqAtomIdx_eq_inter_XPseqCode`, `yPseqAtomIdx_subset_xStepGFst`, `xStepG_snd_eq_inter_XPseqCode`, and `yStepGfst_eq_inter_YPseqCode`’s closed forms ((d)(5)) — a genuinely mechanical but *wide* ripple (every call site of the three theorems needed the extra hypotheses threaded through explicitly, since Lean’s `include`-based implicit-argument mechanism only auto-supplies section variables *within* the section that declares them, not across section boundaries at a call site). `Exercise812e.lean`’s `isComputableSplit_ofBisection` updated to match (`posIdx_spec/negIdx_spec` fields now take an unused `_hne` parameter).

7. **The concrete construction (part 3, 2026-07-06): splitFromBisection itself redesigned.** Key realization: `posIdxFromBisection/negIdxFromBisection` (the *index*-level $\mathbb{N}$ -valued functions) needed **no change at all** — they already compute exactly the right index in the “genuinely nonempty” branch of each field and an unread junk placeholder (`m`) in the “should be $\emptyset$ ” branch. The bug was purely that `splitFromBisection` (the *set*-level function) wrapped **both** branches in `Q.X (...)`, which is never literally $\emptyset$. Fix: route the same two deciders through a three-way `if/else if/else` directly at the `Set  $\gamma \times \text{Set } \gamma$` level — `emptyInterDec` fires $\implies (\emptyset, B')$; else `emptyDiffDec` fires $\implies (B', \emptyset)$; else the genuine bisection (`Q.X (B.left m), Q.X (B.right m)`) — proved well-defined (independent of which witness `Classical.choice` picks for the “presented” existential) via a new bridging lemma `splitFromBisection_eq` (built from `emptyInterDec_congr/emptyDiffDec_congr/B.left_congr/B.right_congr`, the same congruence lemmas `(e)(c)(i)` already supplied). Also generalized the previous “not presented $\rightarrow$ junk (`B', B'`)” fallback (provably wrong in general: $.1 \cap .2 = B' \cap B' = B'$, not $\emptyset$, unless $B' = \emptyset$) to the classical `splitChoice'` (`Exercise812c.lean`) — needed since `SplitSpec'` is stated for **every** `A/Xn : Set  $\alpha$` , not just presented ones, but only free to change since `IsComputableSplit`’s own `posIdx_spec/negIdx_spec` only ever constrain the presented case. `splitFromBisection` gained one new parameter, `hWnomin : W.NoMinimal` (needed to build the `splitChoice'` fallback), threaded through `isComputableSplit_ofBisection` and the concrete instantiations (`Exercise812eD.lean`’s `V_noMinimal`, `Exercise812f.lean`’s `U_noMinimal`). The new `splitFromBisection_isSplitSpec'` theorem needs exactly one hypothesis beyond `isComputableSplit_ofBisection`’s own: `hQne :  $\forall j, Q.X j \neq \emptyset$` , used **only** in the “neither decider fires” branch (to show the bisection’s two halves are each individually non-empty, matching $A \cap Xn \neq \emptyset \leftrightarrow .1 \neq \emptyset / A \setminus Xn \neq \emptyset \leftrightarrow .2 \neq \emptyset$) — not derivable from `ComputableBisection`’s abstract fields alone (nothing there rules out $Q.X (B.left m) = \emptyset$ for an arbitrary `W`), but immediate for both concrete systems from step 2’s “ $Q.X j$ never $\emptyset$ ” fact (`fun j => (VX_nonempty j).ne_empty` for `V`, `fun j => (U_mem_UX j).2.1.ne_empty` for `U`). The two decider-fires branches need no such hypothesis at all — `.1/.2` there are literally $\emptyset/B'$, and the requisite $\leftrightarrow$ s reduce to `hAB` via the algebraic facts $A \cap Xn = \emptyset \rightarrow A \setminus Xn = A$ (resp. $A \setminus Xn = \emptyset \rightarrow A \cap Xn = A$). Concrete instances: `hxSplit812e : SplitSpec' V splitX812e` (`Exercise812eD.lean`) and `hySplit812f : SplitSpec' U splitX812f` (`Exercise812f.lean`), each a direct application of `splitFromBisection_isSplitSpec'` fed the relevant `NoMinimal/IsPositive/DiffClosed` facts plus the nonemptiness closure. `lake build (3175 jobs) clean, zero sorry` project-wide; `#print axioms on hxSplit812e/hySplit812f/splitFromBisection_isSplitSpec'` all give $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (`Classical.choice` pre-existing throughout this file’s open scoped `Classical` — not a new leak).

Exercise 8.12(g)(4)

- **Mathematical Target:** Final assembly — instantiate `Exercise812d.lean`’s `effectiveIso812d` with `D0 := U`, `D1 := V` and `(g)(1)–(3)`’s facts, concluding `UComputablePresentation  $\cong^e$  VComputablePresentation` and closing out Exercise 8.12 in full
- **Lean File:** `Scott1980/Neighborhood/Exercise812g4.lean` (new file, wired into `Scott1980.lean`)
- **Proof Notes:** Fully mechanical, exactly as scoped — a single field-by-field instantiation of `effectiveIso812d` (22 positional arguments: `UComputablePresentation VComputablePresentation U_isComputableDiff V_isComputableDiff splitX812e isComputableSplit_812e splitX812f isComputableSplit_812f U_isPositive U_diffClosed U_noMinimal hxSplit812e V_isPositive V_diffClosed V_noMinimal hySplit812f U_master_nonempty V_master_`

nonempty U_isComputableUnion V_isComputableUnion UX_zero VX_zero), no new proof content of its own — every subgoal `effectiveIso812d` demands was already discharged by (c)–(g) (3). The only wrinkle: `EffectiveIso` lives in the `Scott1980.Neighborhood.Exercise718` namespace (not just `Scott1980.Neighborhood`), needing an explicit `open Exercise718`. `lake build` (3175 jobs) clean, zero sorry project-wide; `#print axioms effectiveIso812_UV` gives $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (same pre-existing baseline as every other `EffectiveIso`-producing def in `Exercise812d.lean/Exercise718.lean`, all of which use `open scoped Classical` throughout — not a new leak).

Exercise 8.13

- **Mathematical Target:** (logicians) Prove U is isomorphic to the domain of all proper filters of the free Boolean algebra on $\aleph_0$ generators (= the Lindenbaum algebra of propositional calculus). (topologists) Connect this representation of U with the collection of non-empty open subsets of $2^{\mathbb{N}}$ (Cantor space).
- **Lean File:** — (scoping investigation only, 2026-07-06, per this project’s discipline for genuinely new pieces; no code written yet); umbrella — see sub-rows **8.13(a)–(c)** below
- **Proof Notes: Scoping investigation, done before writing any code (per explicit user request).** This *is* another “monster” in the 8.12 mold — genuinely new mathematical infrastructure (`grep`-confirmed: **zero** existing Boolean-algebra/filter/propositional-logic/Cantor-space formalization anywhere in `Scott1980/`) — but a key structural discovery makes it *much smaller* than 8.12: **8.13 only asks for a plain isomorphism** ($\cong^D$, `DomainIso`), **never “effective.”** Re-reading `Exercise812c.lean`’s `domainIso812c/isomorphic_812c` (the abstract two-sided back-and-forth lemma 8.12(c) built, $D_0 \cong^D D_1$) confirms it needs **only** plain $\mathbb{N}$ -indexed enumerations $X : \mathbb{N} \rightarrow \text{Set } \alpha$, $Y : \mathbb{N} \rightarrow \text{Set } \beta$ with `IsPositive/DiffClosed/NoMinimal/surjectivity-onto-mem/X 0 = master` — **no** `ComputablePresentat` anywhere. All of 8.12(d)–(g) (the huge majority of that exercise’s ~4,700 lines) existed *purely* to upgrade $\cong^D$ to the effective $\cong^e$ that 8.12’s own statement demands — machinery 8.13 never needs to touch at all. **Second structural discovery, even more load-bearing:** V (`Exercise812.lean`’s `levelSet k m := {n | m.testBit (n % 2^k)}`) **already is** (up to a trivial relabelling) the free Boolean algebra on $\aleph_0$ generators, concretely realized as subsets of $\mathbb{N}$ via “the low-order bits of n .” `levelSet k m` is exactly a finite Boolean combination of the k independent “bit- i ” generators (m ’s bitmask selects which of the 2^k joint valuations of bits $0..k-1$ are included) — and since any finite Boolean combination of *arbitrary*-position bit-generators is a finite union of same- k -prefix classes (pad to a common k , enumerate consistent low-bit patterns), V ’s “non-empty finite unions of $2^{k\mathbb{N}+\ell}$ ” family is *exactly* the full algebra generated by all bit-generators, not merely a sub-fragment. So 8.13’s “logicians” half is expected to reduce to: (i) build the *same* combinatorial structure `levelSet`-style but on $\mathbb{N} \rightarrow \text{Bool}$ (Cantor space) instead of $\mathbb{N}$ — call it `Lindenbaum : NeighborhoodSystem (N → Bool)`, `mem X := ∃ k m, X = cylinderSet k m ∧ X.Nonempty` with `cylinderSet k m := {x : N → Bool | ∀ i < k, x i = m.testBit i}`, a near-verbatim transcription of `levelSet/V`’s existing proofs (`V.no_minimal`, `V.IsPositive`, `DiffClosed`, etc. — expected to port with only the ambient-carrier-type changed, $\mathbb{N}$ ’s `%/testBit` arithmetic mirrored by $\mathbb{N} \rightarrow \text{Bool}$ ’s pointwise $i < k$ prefix-agreement, likely *easier* since no `canonIdx/levelSet_myInter`-style bit-arithmetic normalization is needed for a *plain* isomorphism — that normalization exists only to support V ’s *computable* presentation); (ii) `isomorphic_812c`-style back-and-forth to get `Lindenbaum` $\cong^D V$ (expected close to mechanical, likely *easier* than 8.12(c) itself since both sides are literally the same (k,m) -indexed combinatorial family, just living in different carrier types — may reduce to a direct order-isomorphism $X \mapsto \text{cylinderSet}$ ’s inverse of `levelSet`’s own (k,m) bookkeeping, sidestepping the general back-and-forth

machinery entirely); (iii) compose with the now-`Pass effectiveIso812_UV.toDomainIso` : $U \cong^D V$ (`Exercise812g4.lean`, `Exercise718.lean`’s `EffectiveIso.toDomainIso`) to conclude `Lindenbaum` $\cong^D U$. **Option scoping decision (needs user input before starting code):** how far to push the “= Lindenbaum algebra of propositional calculus” identification literally. **Option A (semantic, smaller):** define the Lindenbaum algebra *directly* as (the quotient of) `Formula` $\mathbb{N}$ (a small inductive AST — `var n/⊤/⊥/¬/∧/∨` — over countably many propositional variables) by **semantic** equivalence ($\varphi \sim \psi := \forall v : \mathbb{N} \rightarrow \text{Bool}, \text{eval } v \varphi = \text{eval } v \psi$), justified by soundness+completeness of classical propositional logic (a standard fact, not reproved) identifying semantic equivalence with provable equivalence — then show $[\varphi] \mapsto \{v : \text{eval } v \varphi = \text{true}\}$ is a Boolean-algebra isomorphism onto `Lindenbaum`’s underlying algebra. Modest addition (`Formula/eval` is a short inductive + recursive `Bool`-eval, no proof calculus needed). **Option B (syntactic, much larger):** build an actual Hilbert-style (or natural-deduction) proof system for propositional logic with $\vdash$, then prove soundness *and* completeness w.r.t. `eval`, then define the Lindenbaum algebra as the genuine syntactic quotient by $\vdash$ -provable-equivalence. This is effectively a full propositional-logic metatheory formalization — likely bigger than 8.12 on its own — and Option A already delivers the *same* final algebra (by the completeness theorem Option B would have to prove anyway) with none of the added machinery. **Recommend Option A** unless the user specifically wants the proof-theoretic development as its own exercise. **Topologists’ half — a genuine finding, not yet a plan:** the literal reading “`Lindenbaum.Element` (proper filters) $\simeq_o$ non-empty open subsets of $2^{\mathbb{N}}$ ” is **false** as stated, for a structural reason worth recording: every `Element` (Scott filter) contains `V.master/Lindenbaum.master` (`Element.master_mem` is a required field, `Basic.lean` line 216), so the naive map $x \mapsto \bigcup \{X : x.\text{mem } X\}$ is constant (always the whole space) — filters do **not** correspond to open sets via *union*. Working out the correct correspondence (via the *opposite* direction, $x \mapsto \bigcap \{X : x.\text{mem } X\}$, using that basic neighbourhoods are clopen in a *compact* space): this **does** biject `Element` with non-empty **closed** sets that are intersections of clopens (all of them, in a zero-dimensional compact space) — order-reversing ($x \leq y \leftrightarrow Z(y) \subseteq Z(x)$), proved via a genuine finite-intersection-property/compactness argument ($Z(x) \subseteq X \rightarrow X \in x$, for X a basic neighbourhood, via extracting a finite subcover of X ’s complement from x ’s “witnessing” family and closing under x ’s existing finite-meet/upward closure — a real two-line-of-math but not-yet-formalized argument). This exactly reflects 8.12’s own aside (“compact = principal”): the **compact/principal** elements are precisely the ones whose $Z(x)$ is clopen (hence open), matching `Definition 1.7`’s **principal** $X \mapsto X$ on the nose; *general* (non-compact) elements correspond to closed, not open, sets. Two live options for what to actually formalize: (i) the precise closed-set duality above (mathematically the “real” content, but doesn’t literally match “open subsets” as worded — would need dualizing via complementation, which turns “non-empty” into “proper” and vice-versa, so *still* doesn’t literally match); (ii) a much more modest (and easily achievable) reading: show `Lindenbaum`’s basic neighbourhoods (`cylinderSet`) are exactly the clopen basis generating `Mathlib`’s standard product topology on $\mathbb{N} \rightarrow \text{Bool}$ (`Pi.topologicalSpace/discrete Bool` factors) — i.e. literally exhibit $\{X \mid \text{Lindenbaum.mem } X\} \cup \{\emptyset\}$ as `IsTopologicalBasis` for that topology — connecting the algebraic ($\mathcal{D}$) and topological (open sets = arbitrary unions of $\mathcal{D}$) pictures without a false isomorphism claim. **Needs a user decision before any code is written** (see `HANDOFF.md`’s matching checkpoint / the chat where this was scoped).

Exercise 8.13(a)

- **Mathematical Target:** V (`Exercise812.lean`) is the domain of proper filters of the free Boolean algebra on $\aleph_0$ (independent) generators; hence $U \cong^D$ that domain
- **Lean File:** `Scott1980/Neighborhood/Exercise813a.lean`

- **Proof Notes:** Landed **simpler than even the already-optimistic scoping estimate**: no new `NeighborhoodSystem` was needed at all — V itself (on $\mathbb{N}$, not $\mathbb{N} \rightarrow \text{Bool}$) already *is* the algebra, avoiding every bit of `cylinderSet/Cantor-space` bookkeeping the scoping row anticipated. Content: `generator i := {n | n.testBit i}` (the $\aleph_0$ generators); `GeneratedBy generator` (a small hand-rolled inductive — `of/univ/inter/union/compl` — the Boolean subalgebra of `Set N` they generate, since no such generic notion exists in `Mathlib` or this project); the headline lemma `V.mem_iff_generatedBy : V.mem X ↔ GeneratedBy generator X ∧ X.Nonempty` (soundness via structural induction on `GeneratedBy`, reusing `V.union_mem/levelSet_inter` for the `union/inter` cases and a new `levelSet_compl` for the `compl` case; completeness via `levelSet_eq_biUnion` decomposing into `affine-pieces`, each a finite intersection of generators/complements via a new `affine_eq_biInter`, reassembled by `Finset.induction_on`); `generators_independent` (every finite Boolean combination of finitely many generators is non-empty — the standard characterization of “freely generates a Boolean algebra,” witnessed directly by `bitmaskOf`). Since `Basic.lean`’s `Element` (upward-closed, finite-meet-closed, contains master, and — because `V.mem` excludes $\emptyset$ — never contains bottom) is *definitionally* “proper filter of $\{X \mid \text{GeneratedBy generator } X\}$ ” once `V.mem_iff_generatedBy` is in hand, `V.Element` is the domain of proper filters of the free Boolean algebra on $\aleph_0$ generators, with zero further translation needed. The headline `exercise813a : U ≅D V` is then literally $\langle \text{effectiveIso812_UV.toDomainIso} \rangle$ (already `Pass`, `Exercise812g4.lean`) — no new back-and-forth argument, exactly as the parent row predicted. New arithmetic lemmas needed along the way (none existed in `Mathlib`): `testBit_mod_two_pow ((n % 2k).testBit i = decide (i < k) && n.testBit i`, via `Nat.testBit_two_pow_mul_add` fed `Nat.div_add_mod`) and `testBit_sum_two_pow/bitmaskOf` (read off a prescribed finite bit-pattern, via `Finset.toFinset_bitIndices_sum_two_pow`, generalizing the same trick `Exercise812.lean`’s `upsample` already used once). `lake build (3176 jobs) clean, zero sorry; #print axioms exercise813a/V.mem_iff_generatedBy/generators_independent all ⊆ {propxt, Classical.choice.quot.sound}`, the same pre-existing baseline as every other fact about V/U in this project.

Exercise 8.13(b)

- **Mathematical Target:** Justify the “= Lindenbaum algebra of propositional calculus” identification: a `Formula/propositional-syntax` bridge from 8.13(a)’s concrete $\{X \mid \text{GeneratedBy generator } X\}$ to an actual quotient of propositional formulas
- **Lean File:** `Scott1980/Neighborhood/Exercise813b.lean`
- **Proof Notes:** Implemented “Option A” (semantic-equivalence quotient, no full proof calculus/soundness/completeness needed). `Formula` (a minimal `var/bot/top/neg/and/or` AST over $\mathbb{N}$ -indexed variables) with two parallel recursions: `evalV : (N → Bool) → Formula → Bool` (standard truth-valuation semantics) and `evalSet : Formula → Set N` (the same recursion, but interpreting `var i` $\mapsto$ `generator i` and Boolean connectives as `Set N` operations — i.e. 8.13(a)’s specific homomorphism). `mem_evalSet_iff : n ∈ evalSet φ ↔ evalV (fun i => n.testBit i) φ = true` is the bridge between them (structural induction, `simp-only`); from it, `generatedBy_iff_exists_evalSet` shows `evalSet`’s range is exactly `GeneratedBy generator` (both directions by induction, `of/univ/inter/union/compl` matching `Formula`’s constructors one-for-one). The one substantive lemma is `semanticEquiv_iff_evalSet_eq`: `SemanticEquiv φ ψ (∀ v, evalV v φ = evalV v ψ` — Scott’s own Lindenbaum equivalence, quantifying over *all* valuations $\mathbb{N} \rightarrow \text{Bool}$) agrees with `evalSet φ = evalSet ψ` (which only ever “tests” the countably many *bit-derived* valuations $n \mapsto (\text{fun } i \Rightarrow n.\text{testBit } i)$) — true because any single formula only mentions finitely many variables (`vars : Formula → Finset N, evalV_eq_of_agree`), so any arbitrary valuation can be swapped for a matching bit-derived one on that finite set, witnessed

directly via `bitmaskOf (exists_bitsOf_agree, reusing 8.13(a)'s testBit_bitmaskOf)`. `Lindenbaum := Quotient formulaSetoid` is then literally *the Lindenbaum algebra of propositional calculus* as a type; `Lindenbaum.toSet := Quotient.lift evalSet ...` is well-defined by the $\Leftarrow$ direction above, `Lindenbaum.toSet_injective` by the $\Rightarrow$ direction (`Quotient.sound`), and `Lindenbaum.range_toSet : Set.range toSet = {X | GeneratedBy generator X} ( $\Rightarrow$  generatedBy_iff_exists_evalSet)` makes `Lindenbaum` $\simeq$ `{X // GeneratedBy generator X}` explicit — i.e. 8.13's parenthetical, “free Boolean algebra on $\aleph_0$ -generators (= Lindenbaum algebra of propositional calculus),” is now a proved bijection, not an assertion. Bonus: `Entails/entails_iff_evalSet_subset` (via the identical finitary argument) shows the bijection also matches semantic entailment with $\subseteq$, i.e. it respects order/the Boolean-algebra structure, not just underlying sets — without needing to bundle a full `BooleanAlgebra Lindenbaum` instance (would need ~10+ axiom lemmas, judged disproportionate to this exercise's actual ask). `lake build (3177 jobs) clean, zero sorry; #print axioms on Lindenbaum.toSet_injective/Lindenbaum.range_toSet/semanticEquiv_iff_evalSet_eq/entails_iff_evalSet_subset all  $\subseteq$  {propxt, Classical.choice, Quot.sound}` — confirmed (by comparison to `#print axioms exercise813a`) the same pre-existing baseline inherited transitively from 8.13(a)/8.12's $\cong^D$ chain, not anything new introduced here.

Exercise 8.13(c)

- **Mathematical Target:** (topologists) Connect 8.13(a)'s filter-domain representation of $\mathcal{U}$ with the non-empty open subsets of Cantor space $2^{\mathbb{N}}$ ($\mathbb{N} \rightarrow \text{Bool}$ with the product topology)
- **Lean File:** `Scott1980/Neighborhood/Exercise813c.lean` (umbrella; user chose the “full Stone duality” scope over the more modest `IsTopologicalBasis`-only reading — see sub-rows **8.13(c1)–(c4)** below, all now **Pass**)
- **Proof Notes:** The literal “proper filters $\simeq$ non-empty opens” reading is **false** (every filter contains `master`, so $\bigcup$ -of-filter is constant; filters correspond, order-reversingly, to non-empty **closed** sets via $x \mapsto \bigcap \{Y : x.\text{mem } Y\}$, using compactness). The reading that actually lands on “opens” (matching Scott's literal word) goes through the *dual* notion — **ideals** (downward-closed, finite-join-closed, proper) — since $\bigcup$ -of-an-ideal-of-clopens is open (not constant), and $Y \mapsto Y^c$ is a Boolean-algebra anti-automorphism turning ideals into filters. Full chain, decomposed into four subgoals: **(c1)** Cantor space's clopen algebra is exactly `GeneratedBy genPoint` (a literal transcription of 8.13(a)'s `generator/GeneratedBy generator`, but on carrier $\mathbb{N} \rightarrow \text{Bool}$ via coordinate-projections `genPoint i := {x | x i = true}`), using compactness + `Mathlib's isTopologicalBasis_pi/isTopologicalBasis_singletons` for the (harder) “every clopen is `GeneratedBy genPoint`” direction; opens are then unions of such clopens. **(c2)** `generator(on  $\mathbb{N}$ )/genPoint(on  $\mathbb{N} \rightarrow \text{Bool}$ )` realize the *same* abstract free Boolean algebra on $\aleph_0$ generators — made precise, with zero new independence argument, by reusing 8.13(b)'s `Formula/Lindenbaum` quotient with a second evaluation `evalSet' : Formula $\rightarrow$ Set ($\mathbb{N} \rightarrow \text{Bool}$) (var i $\mapsto$ genPoint i), giving Lindenbaum $\simeq$ {X | GeneratedBy generator X} and Lindenbaum $\simeq$ {Y | GeneratedBy genPoint Y} simultaneously, hence (composing) an explicit order-isomorphism between the two concrete algebras without needing any bijection of the (very different — countable vs. uncountable) underlying carriers $\mathbb{N}/\mathbb{N} \rightarrow \text{Bool}$. (c3) general small lemma: for a Boolean subalgebra of sets closed under complement, I is a proper ideal iff $\{Y^c : Y \in I\}$ is a proper filter — applied to Cantor clopens. (c4) assembly: non-empty open $0 \mapsto \text{idealOf } 0 := \{Y \mid \text{GeneratedBy genPoint } Y \wedge Y \subseteq 0\}$ (an ideal by (c1)'s clopen-algebra structure, with $\bigcup \text{idealOf } 0 = 0$ since clopens form a basis) $\mapsto$`

(c3) dual filter of Cantor clopens $\mapsto$ (c2) filter of $\mathbb{N}$ -clopens = $\mathbf{V.Element} \mapsto$ (8.13a) element of $\mathbf{U}$. Sub-rows below track (c1)–(c4) individually; not all need to land in the same Lean file. 8.13(c), like (b), remains independently optional — 8.13’s mathematical content is already *Pass* via (a)+(b) — this is purely the topologists’ expository half.

Exercise 8.13(c1)

- **Mathematical Target:** Cantor space $2^{\mathbb{N}}$ ’s clopen algebra is exactly `GeneratedBy genPoint (genPoint i := {x :  $\mathbb{N}$  → Bool | x i = true})`, and every open set is a union of such clopens
- **Lean File:** `Scott1980/Neighborhood/Exercise813c.lean`
- **Proof Notes:** `genPoint i := (fun x => x i) ^{-1} {true}` — literal transcription of 8.13(a)’s generator i onto carrier $\mathbb{N} \rightarrow \text{Bool}$; `isClopen_genPoint` via `isClopen_discrete {true} (Bool’s DiscreteTopology).preimage (continuous_apply i)`. **Easy direction** `generatedBy_genPoint_isClopen`: clopens closed under `GeneratedBy`’s ops, plain structural induction. **Hard direction** (the headline, `isClopen_iff_generatedBy_genPoint`): every clopen Y is `GeneratedBy genPoint`, via compactness — `box I f := {x |  $\forall i \in I, x i = f i$ }` (finite-support basis element); `isOpen_pi_iff` gives, for each $f \in Y$, a finite I with `box I f  $\subseteq$  Y` (shrinking $u i$ to $\{f i\}$, valid since `Bool` is discrete so any set containing $f i$ works and $f i \in u i$ already given); each `box` is `GeneratedBy genPoint (generatedBy_genPoint_box, Finset.induction_on + case-split on f a, mirroring 8.13(a)’s generatedBy_affine)`; Y clopen $\implies$ compact (`IsClosed.isCompact, CompactSpace ( $\mathbb{N} \rightarrow \text{Bool}$ )` free from `Bool`’s finiteness + Tychonoff) extracts a **finite** subcover (`IsCompact.elim_finite_subcover`) of boxes all $\subseteq Y$, so $Y =$ their union, `GeneratedBy genPoint` by `generatedBy_genPoint_biUnion (Finset.set_biUnion_insert` idiom, same as 8.13(a)’s `generatedBy_biUnion_affine`; needed classical for a generic- β `DecidableEq` instance). Corollary `isOpen_iff_exists_iUnion_generatedBy`: opens (not just clopens) are exactly unions of `GeneratedBy genPoint` sets — the “topological basis” content the parent row’s more modest candidate (ii) would have targeted, now obtained as a free corollary of the fuller clopen identification. `lake build` (3178 jobs) clean, zero sorry; `#print axioms` on both headline theorems $\subseteq$ {`propext, Classical.choice, Quot.sound`}, the project’s standard baseline.

Exercise 8.13(c2)

- **Mathematical Target:** `generator( $\mathbb{N}$ )/genPoint( $\mathbb{N} \rightarrow \text{Bool}$ )` realize the same abstract free Boolean algebra on $\aleph_0$ generators — an explicit order-isomorphism $\{X \mid \text{GeneratedBy generator } X\} \simeq_o \{Y \mid \text{GeneratedBy genPoint } Y\}$, mediated by 8.13(b)’s Lindenbaum quotient (a second evaluation `evalSet'`)
- **Lean File:** `Scott1980/Neighborhood/Exercise813c.lean` (same file as (c1), new section)
- **Proof Notes:** `evalSet' : Formula  $\rightarrow$  Set ( $\mathbb{N} \rightarrow \text{Bool}$ )` (8.13(b)’s `Formula`, evaluated via `genPoint` instead of `generator`) — *simpler* than `evalSet`: `mem_evalSet'_iff` needs no bit-encoding step ($x : \mathbb{N} \rightarrow \text{Bool}$ already *is* a valuation, contrast `evalSet`’s $n \mapsto \text{fun } i \Rightarrow n.\text{testBit } i$), so `semanticEquiv_iff_evalSet'_eq/entails_iff_evalSet'_subset` need no finitary agreement argument either (both direct `rw/case-split`, no `exists_bitsOf_agree`-style lemma). `generatedBy_iff_exists_evalSet', Lindenbaum.toSet'/toSet'_injective/range_toSet'` are line-for-line mirrors of 8.13(b)’s versions. Rather than bundling an explicit `OrderIso` (would need a `PartialOrder Lindenbaum` instance lifting

Entails to the quotient, judged disproportionate machinery), the headline is the lighter-weight but equally substantive **Corresponds** $X \ Y := \exists \varphi, \text{evalSet } \varphi = X \wedge \text{evalSet}' \varphi = Y$: witnesses via a common Formula that $\{X | \text{GeneratedBy } \text{genPoint } X\}$ and $\{Y | \text{GeneratedBy } \text{genPoint } Y\}$ are the same algebra — `exists_corresponds_of_generatedBy_genPoint/genPoint` (existence both ways, from `generatedBy_iff_exists_evalSet/evalSet'`), `Corresponds.uniqueness` (uniqueness both ways, via `semanticEquiv_iff_evalSet_eq/evalSet'_eq` composed through `SemanticEquiv`), `Corresponds.subset_iff` (respects $\subseteq$, via both `entails_iff_evalSet_subset` lemmas) — together exactly the data of an order-isomorphism, stated relationally. `lake build (3178 jobs) clean, zero sorry`; axiom baseline unchanged.

Exercise 8.13(c3)

- **Mathematical Target:** For a Boolean subalgebra of sets closed under complement, I is a proper ideal iff $\{Y^c : Y \in I\}$ is a proper filter
- **Lean File:** `Scott1980/Neighborhood/Exercise813c.lean` (same file as (c1)/(c2), new section)
- **Proof Notes:** A g -generic toolkit (not Cantor-specific — works for any $\{\alpha : \text{Type}^*\}/g : \mathbb{N} \rightarrow \text{Set } \alpha$): `dualFilter x := {Y | Yc ∈ x}` ($Y \mapsto Y^c$ applied to a whole family; `dualFilter_dualFilter` records it as its own inverse). Rather than bundling `IsIdealOf/IsFilterOf` structures, each of the four defining properties is its own small lemma taking exactly the hypothesis it needs, chosen to match `Basic.lean`'s `Element` fields one-for-one so 8.13(c4) could assemble a literal `V.Element` term directly from them: `generatedBy_of_mem_dualFilter` (membership in `GeneratedBy g` propagates, via `GeneratedBy.compl`), `univ_mem_dualFilter` (an ideal containing $\emptyset$ dualizes to a filter containing `univ`), `not_empty_mem_dualFilter` (an ideal excluding `univ` dualizes to a filter excluding $\emptyset$), `inter_mem_dualFilter` (join-closed ideal dualizes to meet-closed filter, via $(Y \cap Z)^c = Y^c \cup Z^c$), `up_mem_dualFilter` (downward-closed ideal dualizes to upward-closed filter, via $Z \subseteq Y \leftrightarrow Y^c \subseteq Z^c$) — each a one-line De Morgan argument. `lake build (3178 jobs) clean, zero sorry`; axiom baseline unchanged.

Exercise 8.13(c4)

- **Mathematical Target:** Assembly: non-empty open $0 \subseteq 2^{\mathbb{N}} \mapsto \text{idealOf } 0 \mapsto$ (c3) dual filter $\mapsto$ (c2) filter of $\mathbb{N}$ -clopens = `V.Element` $\mapsto$ (8.13a) element of U
- **Lean File:** `Scott1980/Neighborhood/Exercise813c.lean` (same file as (c1)–(c3), final section)
- **Proof Notes:** `idealOf 0 := {Y | GeneratedBy genPoint Y ∧ Y ⊆ 0}` (the clopens inside 0) is a proper ideal exactly when $0 \neq \text{Set.univ}$ (`empty_mem_idealOf`, `univ_not_mem_idealOf`, `union_mem_idealOf`, `down_mem_idealOf`); dualizing (8.13(c3)'s toolkit) gives a proper filter of `GeneratedBy genPoint`; three more `Corresponds` helpers (`generatedBy_left/right`, `nonempty_iff` — via $n \mapsto \text{fun } i \Rightarrow n.\text{testBit } i$ directly for $\rightarrow$, `exists_bitsOf_agree` for $\leftarrow$, mirroring 8.13(b)'s finitary argument — and `inter`) transport it through 8.13(c2)'s `Corresponds` to a proper filter of `GeneratedBy generator`; `elementOfOpen` assembles this directly as a genuine `V.Element` term (all four `Basic.lean` `Element` fields — `sub/master_mem/inter_mem/up_mem` — discharged from the toolkit, no new axioms), hence (via `exercise813a`) an element of U . **Corrected Scott's own phrasing en route:** “non-empty” is, taken literally, the *wrong* exclusion for this construction — `idealOf 0 = {0}` dualizes just fine, to the legitimate (if degenerate) **bottom** element of U ; what actually breaks properness is $0 = \text{Set.univ}$ (forces the dual filter to contain $\emptyset$, forbidden by `V_mem_iff_generatedBy`). The precise hypothesis is $0 \neq \text{Set.univ}$ (“proper”),

documented prominently in the file; Scott’s remark is informal here, consistent with the parallel “opens vs. closes” imprecision already flagged in the parent row. lake build (3178 jobs) clean, zero sorry; axiom baseline unchanged.

Exercise 8.14

- **Mathematical Target:** *closure operators* ($I \sqsubseteq a$); fixed-point set finitary; what are the finite elements
- **Lean File:** Scott1980/Neighborhood/Exercise814.lean
- **Proof Notes:** `IsClosureOperator a := IsRetraction a ∧ idMap E ≤ a (I_E ⊆ a`, i.e. a inflationary — `le_toElementMap_of_isClosureOperator`). Main theorem **isFinitary_of_isClosureOperator**: for any closure operator $a : E \rightarrow E$, $\text{Fix}(a)$ (`FixSet a`, from `Theorem85.lean`) is finitary. Strategy: identify the compact elements of $\text{Fix}(a)$ as exactly $a(\uparrow X)$ for E -neighbourhoods X (`IsCompactFix`, `isCompactFix_toElementMap_principal` — via inflation + E ’s own `principal_isCompactElt`), show finite bounded joins of compacts are compact (`isCompactFix_sup`, via Exercise 1.27’s `sSup/le_sSup/sSup_le`), then build a genuine `NeighborhoodSystem` **domainOfClosure** whose tokens are `CompactFix h` (the compact fixed points) and whose neighbourhoods are principal up-sets `upFix` (smaller compact $\implies$ bigger up-set, matching the information order); `inter_mem` is exactly `upFix_inter` (intersection of two up-sets = up-set of the join). The order isomorphism `fixSetOrderIso : FixSet a ≃o (domainOfClosure h).Element` goes via `toElementFilter/fin` (directed union, over `confirmedIdx`, of all compacts confirmed by a filter), with round-trips `toElementFilter_fromElementFilter/fromElementFilter_toElementFilter` — the latter using E ’s algebraicity transported through a (`toElementMap_eq_iSupDirected_genFamily`: y is the directed union of $a(\uparrow X)$ for $X \in y$, from applying a to `eq_iSupDirected_principal`). **Finite elements answered exactly** (`isCompactFix_iff`): $y \in \text{Fix}(a)$ is compact iff $y = a(\uparrow X)$ for a single E -neighbourhood X — a sandwich argument pulling one witness X out of the directed decomposition via compactness. The “give examples on PN” prompt is expository and left as an optional non-blocking follow-up (not needed for the exercise’s actual imperative). lake build (2955 jobs) clean, zero sorry; #print axioms on `isFinitary_of_isClosureOperator/isCompactFix_iff/fixSetOrderIso ⊆ {propext, Quot.sound}`, choice-free.

Exercise 8.15

- **Mathematical Target:** Give a *direct* proof that $\{X \mid X \triangleleft D\}$ is effectively presented if D is. (Hint: the finite elements of the domain correspond exactly to the finite systems $X \triangleleft D$.) For $D = \mathcal{U}$, show the computable elements correspond exactly to the effectively presented domains (up to effective isomorphism).
- **Lean File:** Scott1980/Neighborhood/Exercise815.lean (complete: both halves done, choice-free modulo the pre-existing UX artifact; 6g deliberately out of scope, documented in-file)
- **Proof Notes:** direct (non-Exercise222) construction. Fix a `ComputablePresentation` P of D . For a finite index list `js : List ℕ`, the *finitely generated subsystem* `Fin(js) := {Y | ∃ sub ⊆ js, D.mem Y ∧ Y = interFrom P D.master sub}` (reusing `Theorem75.lean`’s `interFrom`) is itself a subsystem `finGenSys(js) < D` (closure under consistent intersection: combine two sub-selections by `list-filter`, no bitmask needed at this layer). The **key algebraic fact** (`Fin_concat_le_iff`): for any $D' \triangleleft D$, $\text{Fin}(js_1 ++ js_2) \subseteq D'.\text{mem} \leftrightarrow \text{Fin}(js_1) \subseteq D'.\text{mem} \wedge \text{Fin}(js_2) \subseteq D'.\text{mem}$ — proved via `interFrom_mem_of_witness` (any intermediate partial meet along a consistent chain is itself consistent, using the *full*

meet as the witness) + `D'.inter_closed`. Iterating over singletons gives **Fin_le_iff_forall_mem**: $\text{Fin}(js) \subseteq D'.\text{mem} \leftrightarrow \forall i \in js, D'.\text{mem} (P.X i)$ — the workhorse for everything downstream.

The domain. Token type `List ℕ`; `SubD.mem N := ∃ js, N = nbhd(js)` where `nbhd(js) := {js' | Fin(js) ⊆ Fin(js')}` (anti-monotone principal up-set, mirroring `Exercise222.nbhd`). `nbhd(js1) ∩ nbhd(js2) = nbhd(js1 ++ js2)` is exactly `Fin_concat_le_iff` instantiated at `D' := finGenSys(js')`. `nbhd(a) = nbhd(b) ↔ Fin(a) = Fin(b)` (antisymmetry, `a ∈ nbhd(a)` reflexive).

The isomorphism `SubD.Element` $\simeq_o \{D' \mid D' \triangleleft D\}$ (fully choice-free — an improvement on `Exercise222`'s classical route!): forward `D' ↦ (fun N ↦ ∃ js, N = nbhd(js) ∧ ∀ i ∈ js, D'.mem (P.X i))`; backward `x ↦ (fun Y ↦ ∃ js, x.mem (nbhd js) ∧ Y ∈ Fin(js))`. Round trips use `Fin_le_iff_forall_mem` plus a finite fold combining witnesses over the (finite) list `js` via repeated `x.inter_mem` (concatenating confirmed generators) — no need for `Exercise222`'s `Cl`/arbitrary-finite-subset machinery or `Classical.choice`.

Computability. `X n := nbhd(decodeList n)`. `cons_computable/inter/inter_spec` are **free**: `nbhd(js1) ∩ nbhd(js2) = nbhd(js1 ++ js2)` *exactly* (not just $\subseteq$), so `appendListCode n m` is always a valid (in fact exact) witness/index, no consistency case-split needed. Only `interEq_computable` (deciding *equality* `Fin(A) = Fin(B)`) needs real content: a “`P.X m ∈ Fin(decodeList c)`” decider via `Theorem75.lean`'s Milestone 3 apparatus (`bitSelect` + a new `idxCharAt` device reusing `consCharAt`'s fold but projecting the index component instead of the flag, since that component's update is independent of the flag) bundled through `RecDecidable.bExists/RecDecidable2.bForallList` (`Recursive.lean`) to reach `Fin(A) ⊆ Fin(B)`, then both inclusions via `Set.Subset.antisymm_iff` give equality. `cons_computable/inter/inter_spec` assembled from `SubDX_inter_eq` (exact, unconditional); `masterIdx := encodeList []`. Capstone `subsystem_isEffectivelyGiven_of_isEffectivelyGiven`: `D.IsEffectivelyGiven → ∃ V, V.IsEffectivelyGiven ∧ Nonempty (V.Element` $\simeq_o \{D' \mid D' \triangleleft D\})$, combining `SubDPresentation` with the `subsystemIso` order isomorphism — **the first half of Exercise 8.15, done directly and choice-free** (`#print axioms` on every new theorem $\subseteq \{\text{proptext}, \text{Quot.sound}\}$).

Second half ($D = \mathcal{U}$), Subgoal 6 — plan (worked in sequence). Fix `UP := UComputablePresentation` and `x : (SubD UP).Element`; write `D'x := toSubsystemSys UP x (D'x < Δ U` via `toSubsystemSys_subsystem`). A key mathematical subtlety, found while planning: for an *arbitrary* abstract `Q : ComputablePresentation` `D'x` unrelated to `UP`, deciding `Q.Xn ⊆ UP.Xm` needs a cross-presentation comparison that the `ComputablePresentation` axioms do **not** provide (two numberings of the same set need not be effectively comparable without extra structure — a genuine phenomenon, not a gap in this codebase; a disjoint-interval example shows `x.mem (nbhdGen UP js)` does **not** imply `U.mem (interFrom UP U.master js)` in general, e.g. `js` naming two disjoint rational intervals). So the second half is formalized **relative to UP's own enumeration** (the natural, provable reading of “up to effective isomorphism”), in sub-subgoals:

- **6a** ✓ (index-set reduction, `subsystemU_computable_iff_index_set_re`): `IsComputableElement (SubDPresentation P) x ↔ REPred (fun i => D'x.mem (P.X i))`, via `mem_nbhdGen_iff` + `REPred.forall_mem_decodeList` (and its converse, reindexing along the primitive-recursive singleton-list code `i ↦ encodeList [i]`).
- **6b–6d** ✓ (combined into one theorem, `subsystemU_element_computable_iff`): `x computable ↔ ∃ r, Nat.Primrec r ∧ ∀ i, D'x.mem (P.X i) ↔ ∃ n, r n = i` — $\rightarrow$ via `Exercise714.repred_exists_primrec_range` (witness `a := P.masterIdx`), $\leftarrow$ via `Exercise714.repred_range_primrec`. Both choice-free (`#print axioms` $\subseteq$

- `{propext, Quot.sound}`), and — like Subgoals 1–5 — stated generically in `D/P` (never needed `D =  $\mathcal{U}$` specifically).
- **6e (enumeration half) ✓**. Specializing to `P := UComputablePresentation (D := U)` as planned, two $\mathcal{U}$ -specific lemmas unlock the construction: `UX_Uinter_dichotomy` — `UX (Uinter n m) = U.master  $\vee$  UX (Uinter n m) = UX n  $\cap$  UX m`, *unconditionally* (proved via `canonList`’s `filter-nil/cons` cases; the fallback triggers exactly when the raw pairwise intersection is empty, since both `UX n`, `UX m  $\subseteq$  Set.Ico 0 1` already, making the clip a no-op) — and `toSubsystemSys_mem_foldl_Uinter` — folding `Uinter` from a `D’x.mem` accumulator along a `D’x.mem`-generator list stays `D’x.mem`, by induction combining `finGen` witnesses via `interFrom_append_eq` (true-intersection branch) or `D’x.master_mem` (fallback branch). Crucially, **the branch only ever appears inside the proof, never inside the definition of the enumeration** — this is exactly what defeats the Prop-to-data-extraction obstacle flagged for 6e in the previous checkpoint: `Uinter`’s arithmetic unconditionally “does the right thing” (dichotomy), so no data-level case split on a `RecDecidable` flag is ever needed. With these in hand: `Q’X r n` folds `Uinter  $\circ$  r` over the list coded by `n` via `Recursive.lean`’s **existing, generic** `foldCode` engine (`Q’Xcode r := foldCode (QstepFn r) 0 UP.masterIdx`, primitive recursive via the already-proved `primrec_foldCode` — no new fold-primitive-recursiveness machinery needed). `Q’X_eq` identifies `Q’X r n` with the *generic* `Theorem75.idxchain UP (map r (decodeList n))`, giving: `Q’x_mem_X` (every `Q’X r n` is `D’x.mem`, via `toSubsystemSys_mem_foldl_Uinter`) and `Q’x_surj` (every `D’x`-neighbourhood is some `Q’X r n`, via the *generic* `idxchain_spec` plus a new choice-free list-level preimage lemma `exists_preimage_of_forall_mem`). All choice-free (the `Classical.choice #print` axioms shows for anything touching `UX` is `Definition87.lean`’s already-documented, pre-existing `Mathlib-Q`-order artifact, confirmed by auditing `U_mem_UX` directly — not anything new here).
 - **6e (inter/cons_computable) ✓** — resolved by a **binary term algebra**. The obstacle above was a *different* problem from the Prop-extraction issue (fully avoided by `Q’X/Q’Xcode` being directly-defined functions throughout) — it was purely arithmetic: `Uinter`’s fallback is not “conservative”, so list-code concatenation (`Q’inter r n m := encodeList (decodeList n ++ decodeList m)`) fails `inter_spec`, and the alternative fix (`Uinter (Q’Xcode r n) (Q’Xcode r m)`) repairs `inter_spec` but breaks `cons_computable` (its witness needs to be *in Q’X’s own index type*). **The fix**: stop indexing `D’x`’s neighbourhoods by lists folded through `Uinter`, and instead index them by a **binary term algebra** — `leafCode j  $\mapsto$  r j`, `nodeCode t1 t2  $\mapsto$  Uinter (val t1) (val t2)`, `masterCode  $\mapsto$  masterIdx`, `Nat.pair`-encoded (`TermAlgebra` section) — so that combining two already-built codes is *literally* the node constructor, staying inside the index type by construction (no search needed to name the combined index). Evaluating a code needs **course-of-values recursion** (a node’s two children are only known $\leq$ the parent via `Nat.unpair`, not decreasing by a fixed amount); this reuses the *already-built, generic* `fuelTable/fuelTable_eq_of_recursion/primrec_fuelTable` machinery from `Recursive.lean` (built there for `decodeFuel10kChar/autStateCardFuelChar`), giving a fuel-free evaluator `TreeVal` with unfolding lemmas at each constructor (`TreeVal_leaf/_node/_master`, plus tag-generic forms `TreeVal_of_tag0/_tag1/_tag_ge2` for the `mem_X` induction) and primitive recursiveness (`primrec_TreeVal`). `Q2X r c := UX (TreeVal r c)` re-proves `mem_X` (strong induction on `c`, tag-dispatch, reusing `UX_Uinter_dichotomy/nbhdGen_inter/interFrom_append_eq` exactly as `toSubsystemSys_mem_foldl_Uinter` did) and `surj` (bridged to the already-proven list-based `Q’x_surj` via `listToTreeAux`, a fold-shaped embedding `List  $\mathbb{N} \rightarrow \mathbb{N}$` with `TreeVal r (listToTreeAux acc`

- 1) = 1.foldl1 (fun a j => Uinter a (r j)) (TreeVal r acc), identified with idxchain's own fold via List.foldl_map — no fresh combinatorial work). **The crux:** Q2inter n m := nodeCode n m now satisfies inter_spec and cons_computable simultaneously — Uinter_spec applies exactly when the consistency hypothesis holds, so UX_Uinter_dichotomy's fallback branch provably never fires on this witness, for *either* field. interEq_computable is a pure reindexing of U_interEq_computable along the primitive-recursive TreeVal r (mirroring ComputablePresentation.reindex pattern, minus the involution — .comp only composes forward). All choice-free modulo the same pre-existing UX/Definition87.lean Mathlib-Q-order Classical.choice artifact (confirmed by auditing Q2x_mem_X/Q2x_surj/Q2_interEq_computable/Q2_cons_computable/Q2inter_spec directly — nothing new).
- **6f (capstone IsEffectivelyGiven) ✓.** Q'xPresentation assembles Q2X/Q2x_mem_X/Q2x_surj/Q2_interEq_computable/Q2_cons_computable/Q2inter/Q2inter_spec/masterCode/Q2X_masterIdx_spec into a genuine ComputablePresentation (toSubsystemSys UP x). subsystemU_effectivelyGiven_of_isComputableElement: if x is a computable element of SubD UP, then D'x := toSubsystemSys UP x is effectively given — completing, for D = $\mathcal{U}$, the “computable elements correspond to effectively presented domains” half of Exercise 8.15, relative to UP's own enumeration.
 - **6g:** record explicitly (in-file and here) that the fully general converse — *every* abstract presentation of D'x is effectively isomorphic to the UP-relative one 6e/6f built — is **deliberately not attempted**: it is a deeper “uniqueness of computable numberings” fact (Rogers-style), is genuinely what Scott's “(up to effective isomorphism)” parenthetical is doing work for, and is out of scope here.

Exercise 8.16

- **Mathematical Target:** for finitary projections $a, b: E \rightarrow E$, $a \sqsubseteq b \leftrightarrow D_a \triangleleft D_b$ where $D_a = \{X \in E \mid X \sqsubseteq aX\}$; if E is effectively given and $a: E \rightarrow E$ is computable, then D_a is effectively given
- **Lean File:** Scott1980/Neighborhood/Exercise816.lean
- **Proof Notes:** Both halves were already (nearly) proved by existing machinery, so this is a thin assembly. D_a is exactly Theorem 8.5's fixedNbhd a. Part 1 (isFinitaryProjection_le_iff_fixedNbhd_subsystem) restricts Theorem 8.6(a)'s order-isomorphism finitaryProjectionSubs : $\{f \mid \text{sub } f = f\} \simeq \{D \mid D \triangleleft E\}$ (where $\leq$ on the right is literally $\triangleleft$, Prop 6.11) from sub-fixed points to finitary projections via sub_eq_self_iff_isFinitaryProjection, assembled from OrderIso.monotone/.symm.monotone/.symm_apply_apply rather than the generated map_rel_iff (to sidestep guessing Mathlib's implicit-argument names). Part 2 is *already* Theorem 8.8(c)'s fixedNbhd_isEffectivelyGiven (Theorem88m.lean) in full generality — IsComputableMap P P a for any ComputablePresentation P of any E already packages “E effectively given via P, a computable relative to P” — so Part 2 needed no new proof, only a restatement under the exercise's name (exercise_8_16). Choice-free ($\subseteq \{\text{propext}, \text{Quot.sound}\}$).

Exercise 8.17

- **Mathematical Target:** find explicit projection pairs for $\mathcal{U} + \mathcal{U}$, $\mathcal{U} \times \mathcal{U}$, $\mathcal{U} \rightarrow \mathcal{U}$ needed for 8.9; are any of these isomorphic to $\mathcal{U}$?; find a universal domain $V \neq \mathcal{U}$
- **Lean File:** Scott1980/Neighborhood/Exercise817.lean

- **Proof Notes: Part 1** (projection pairs) was already answered by `Definition89.lean`'s `iPlus/jPlus`, `iTimes/jTimes`, `iArrow/jArrow` (via `theorem_8_8_b_strong`); this file restates them under 8.17's name and adds the free bonus corollary `sumUU_triangleleftteq_U/prodUU_triangleleftteq_U/funSpaceUU_triangleleftteq_U : (·) ≤ U` (Lemma 6.15 applied to those exact pairs). **Part 3** (a universal $V \neq U$) is answered in full: Exercise 8.12's V (a *different* `NeighborhoodSystem` N , not U 's Q) is effectively isomorphic to U (`effectiveIso812_UV`), and universality transports along isomorphism (`isUniversal_of_isomorphic`), so V is also universal (`V_isUniversal`). This needed one new general-purpose tool not yet in the codebase: `≤ is transitive` (`triangleleftteq_trans`), built via a small local heterogeneous `ProjPair` bundle (`ProjPair.ofSubsystem` from Prop 6.12, `ProjPair.ofIso` from Theorem 2.7's `ofIso` — built via `le_iff_toElementMap_le` rather than the classical `ext_of_toElementMap`, to stay choice-free — and `ProjPair.comp`), composed and fed to Lemma 6.15's `triangleleftteq_of_projectionPair`. **Part 2** (is $U+U/U \times U/U \rightarrow U \cong U$?) is **deliberately deferred**, documented rather than guessed at: only the one-directional embeddings `≤ U` come for free; genuine isomorphism would need a converse embedding plus a back-and-forth argument of the same scale as Exercise 8.12's 7-part development, and Scott's own parenthetical ("the author does not know a really good construction for $U \rightarrow U$ ") flags that even he did not resolve the $\rightarrow$ case. `lake build` (whole project) green, zero sorry. Axiom audit: `triangleleftteq_trans/triangleleftteq_of_isomorphic_left/isUniversal_of_isomorphic` fully choice-free ($\subseteq \{\text{propext}, \text{Quot.sound}\}$); the U/V -mentioning corollaries (`U_isUniversal`, `V_isUniversal`, the three `≤ U` bonuses) inherit `Classical.choice` only from U 's own pre-existing Rat-order-instance provenance, same footprint as every other U -mentioning headline theorem.

Exercise 8.18

- **Mathematical Target:** establish the unproved cases of 8.10
- **Lean File:** `Scott1980/Neighborhood/Exercise818.lean`
- **Proof Notes:** Every case of **Proposition 8.10** — all three combinators $+/\times/\rightarrow$, both halves (**projection-preservation** and **finitary-preservation-with-isomorphism**) — was already fully established by `Proposition810.lean` (`isProjection_sumComb/isProjection_prodComb/isProjection_arrowComb/isProjection_combinators`) and `Proposition810b.lean` (`finitaryProjection_sumComb/finitaryProjection_prodComb/finitaryProjection_arrowComb/finitaryProjection_combinators`, plus explicit isomorphisms `sumComb_elementIso/prodComb_elementIso/arrowComb_elementIso`). Scott's text left several cases (most plausibly $+/\rightarrow$, which needed genuinely new `sumMap/expMap` bifunctor infrastructure beyond the "obvious" $\times$ case) as reader exercises, but this project closed all of them while formalizing Proposition 8.10 itself — so Exercise 8.18 needed **zero new proof content**, only assembling both halves into one headline `exercise_8_18` under this exercise's name. `lake build` (whole project) green, zero sorry, zero new warnings. Axiom audit: $\subseteq \{\text{propext}, \text{Classical.choice}\}$ identical to Proposition 8.10's own footprint (inherited from U , nothing new).

Exercise 8.19

- **Mathematical Target:** consequences of two known facts
- **Lean File:** `Scott1980/Neighborhood/Exercise819.lean`
- **Proof Notes:** Reading "we know T " as " $T \leq E$ " (the natural companion to $E \rightarrow E \leq E$), the answer is **yes**, both $E+E \leq E$ and $E \times E \leq E$ follow. **Products:** $T \leq E$ gives

$E \times E \trianglelefteq (T \rightarrow E)$ via pairing-up-as-a-T-indexed-function (`pairToFun/funToPair`, using Exercise 3.26’s `cond`), and $T \trianglelefteq E$ gives $(T \rightarrow E) \trianglelefteq (E \rightarrow E)$ via `expMap`’s new contravariant monotonicity lemma `expMap_mono_left (funSpace_dom_triangleleftteq)`; chaining with $E \rightarrow E \trianglelefteq E$ and $\trianglelefteq$ ’s transitivity (Exercise 8.17) gives $E \times E \trianglelefteq E$ (`prod_triangleleftteq_of`). **Sums:** $T \trianglelefteq E$ gives $E + E \trianglelefteq T \times (E \times E)$ (tag-and-split via `whichMap/outMap0/outMap1`, inverse `condSum`; two new “cross” round-trips `outMap1_comp_inMap0/outMap0_comp_inMap1` companion Exercise 3.18’s own-side round-trips) and $T \times (E \times E) \trianglelefteq E \times (E \times E)$ (new covariant-in-both-arguments functoriality lemmas `prod_left_triangleleftteq/prod_right_triangleleftteq`, the latter via `prod`’s commutativity isomorphism, Exercise 3.15); composing with $E \times E \trianglelefteq E$ (applied twice, to peel off each product layer) and transitivity gives $E + E \trianglelefteq E$ (`sum_triangleleftteq_of`). One genuine subtlety: `TD.bot` (Exercise326.TD, i.e. `Example12.neighborhoodSy` and `Example23.botElt`) are the *same* element but not `rfl`-unifiable through the `abbrev` chain (dot-notation field projection doesn’t delta-reduce transparently); proved instead by antisymmetry (`TD.bot_eq_botElt`). `lake build` (whole project) green, zero `sorry`, zero new warnings. Axiom audit: `exercise_8_19` $\subseteq$ `{propext, Classical.choice, Quot.sound}`, the same pre-existing footprint as every other `T/cond`-mentioning theorem (from `ext_of_toElementMap` inside `expMap`’s defining lemmas and from `T`’s concrete presentation, Example 1.2), not something new.

Exercise 8.20

- **Mathematical Target:** $D \trianglelefteq D + D$; what about other constructs?
- **Lean File:** `Scott1980/Neighborhood/Exercise820.lean`
- **Proof Notes:** $D \trianglelefteq D \times D$ and $D \trianglelefteq (D \rightarrow D)$ both hold **unconditionally, for every domain** D (no hypotheses needed, unlike Exercise 8.19’s $E \times E \trianglelefteq E$), by the simplest possible combinator recipes, formalized slightly generally over two domains A, B : **product** — embed $a \mapsto \langle a, \perp \rangle / b \mapsto \langle \perp, b \rangle$ (`paired (idMap _) (constMap _ bot)`), retract with `proj0/proj1 (triangleleftteq_prod_fst/triangleleftteq_prod_snd`, Proposition 3.2(i)’s `pair_le_pair_iff` reduces the inequality half to $\perp \leq z.\text{snd}$); **function space** — embed $b \mapsto (\lambda_. b)$ (`curry (proj0 B A), constFunMap`), retract by evaluating at $\perp$ (`evalMap` composed with a constant-at- $\perp$ pairing, `evalBotMap`), with the inequality half following from **monotonicity of approximable maps** (`toElementMap_mono`, Prop 2.2(iii)) applied to $\perp \leq x$. Specializing $A=B=D$ gives the two $\trianglelefteq$ facts (`D_triangleleftteq_prod/D_triangleleftteq_funSpace`, bundled as `exercise_8_20`). $D \trianglelefteq D + D$ itself is treated as background (Scott states it as already known, not part of the question) and not re-derived. **Multiplicity:** for products, the two constructions are already provably *different maps* whenever D has an element $\neq \perp$ (`embedFst_ne_embedSnd_of_ne_bot`, via `fst_pair`) — so yes, more than one in general; for $D \rightarrow D$, the “evaluate at a fixed point” half is forced to be $\perp$ (any other fixed point a would need $a \leq x$ for *every* x), but automorphism-conjugates of the one construction shown give further pairs whenever $\text{Aut}(D)$ is nontrivial (recorded as a discussion point, not formalized, since it depends on D ’s own automorphism group). **Computability:** every combinator used ($\perp$, `paired`, `proj0/proj1`, `curry`, `evalMap`, `constMap`) has (or trivially would have) an `IsComputableMap` closure lemma elsewhere in the project (`Theorem74.lean/Theorem75.lean`), so both pairs are computable whenever D is effectively given — recorded as a citation-backed answer rather than reformalized (assembling the precise $\mathbb{N} \rightarrow \mathbb{N}$ encoding parameters those lemmas expect is bookkeeping proportional to a full computable-presentation transport, disproportionate to this exercise). `lake build` (whole project) green, zero `sorry`, zero new warnings. Axiom audit: **every theorem in this file, including the two headline $\trianglelefteq$ facts, is fully** $\subseteq$ `{propext, Quot.sound}` (no `Classical.choice` at all) — even the map *equalities* were proved via `le_antisymm` on `le_iff_toElementMap_le`-unfolded goals rather than

the choice-tainting `ApproximableMap.ext_of_toElementMap`, since both $\leq$ -directions are literal equalities of `toElementMaps`, not just comparisons (per the project’s stated choice discipline).

Exercise 8.21

- **Mathematical Target:** a computable operator $\lambda a.a\$$ on finitary projections, with $D_{\{a\}} \cong (D_a)\$$
- **Lean File:** — (umbrella; see sub-rows 8.21(a)–(c) below for the per-part Lean files)
- **Proof Notes:** split into 8.21(a) (construction + computability + half of projection-closure — **Pass**), 8.21(b) (the other half of projection-closure, idempotence — **Pass**), and 8.21(c) (the headline isomorphism $D_{\{a\}} \cong (D_a)\$$ — **Pass**). See sub-rows for full detail.

Exercise 8.21(a)

- **Mathematical Target:** construct $\lambda a.a\$$, show it is computable, and prove $a \leq I \implies a\$ \leq I$ (half of “ a a projection $\implies a\$$ a projection”)
- **Lean File:** `Scott1980/Neighborhood/Exercise821.lean`
- **Proof Notes:** The construction of $a\$$ and its tractable properties. $U\$ \trianglelefteq U$ (`dsharpU_trianglelefteq_U`): `dsharpPresentation` (Prop 7.7) makes $U\$$ effectively given, so `theorem_8_8_b_strong` hands it a computable projection pair $iSharp : U\$ \rightarrow U / jSharp : U \rightarrow U\$$, exactly Definition 8.9’s own i_+ / j_+ etc. recipe. **The operator** (`aSharp`): Scott’s $a\$$ should satisfy $a\$(x\$) = (a\ x)\$$ and $a\$(y, z) = \langle a\$ y, a\$ z \rangle$ — precisely the two defining equations (`gMap_in/gMap_pair`) of Exercise 7.17 Part 2’s catamorphism `gMap` specialized to $u := \text{in} \circ a$, $v := \text{pair}$, so the “fixed-point construction” the exercise asks for is already on hand as `gMap`: $aSharpInner\ a := gMap\ (\text{in}SharpMap.comp\ a)\ \text{pair}SharpMap\ hU : U\$ \rightarrow U\$$, $aSharp\ a := iSharp \circ aSharpInner\ a \circ jSharp : U \rightarrow U$, mirroring Definition 8.9’s conjugation-through-a-projection-pair pattern. **Computable** (`aSharp_isComputable`): `gMap_isComputable` applies directly since `in/pair` are computable, chained through `iSharp/jSharp`’s own computability. $a \leq I \implies a\$ \leq I$ (`aSharp_le_idMap_of_le`, half of “ a a projection $\implies a\$$ a projection”, Prop 8.10’s $a \sqsubseteq I \implies a + b \sqsubseteq I + I = i \circ j \sqsubseteq I$ recipe transcribed to $\$$): needs two new general tools — `gMap_mono` (monotonicity of the catamorphism in u, v , by direct structural induction on the `GRel` derivation parallel to `gRel_mono`, using `ApproximableMap.le_iff`’s unfolding of $\leq$ to pointwise relation inclusion) and `gMap_inSharp_pairSharp_eq_idMap` (`gMap_in\ pair = I_{\{D\}}`, by two structural inductions — on `GRel` and on `MemS` — mirroring `gMap_in/gMap_pair`’s own style). `lake build` (whole project) green, zero sorry. Axiom audit: `dsharpU_trianglelefteq_U/aSharp_isComputable/aSharp_le_idMap_of_le` $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (inherited from U , not new, matching `Definition89.lean/Proposition810.lean`’s baseline); the two new general tools `gMap_mono/gMap_inSharp_pairSharp_eq_idMap` are fully choice-free $\subseteq \{\text{propext}, \text{Quot.sound}\}$.

Exercise 8.21(b)

- **Mathematical Target:** the other half of “ a a projection $\implies a\$$ a projection” — idempotence $a = a \circ a \implies a\$ = a\$ \circ a\$$, completing `isProjection_aSharp` (Proposition 8.10’s recipe, transcribed to $\$$, for the retraction half rather than the $\leq I$ half already done in 8.21(a))
- **Lean File:** `Scott1980/Neighborhood/Exercise821.lean`

- **Proof Notes:** Unlike $\times/\rightarrow/+$ in `Proposition810.lean`, there is no elementwise closed form for `gMap`’s action on a *general* element of `D$` (its elements can be infinite trees, unlike `pair/fst/snd` or `curry/eval`, which have one-step defining equations valid everywhere), so this needs a genuine catamorphism-uniqueness lemma. All four planned sub-steps closed: **8.21(b)(1)** — `gMap_eq_of_satisfies` (the uniqueness-of-catamorphism lemma: any *strict* $k : D_{\text{sharp}} D \text{ hD} \rightarrow E$ satisfying `gMap`’s two defining equations at the element level equals `gMap u v hD` outright). Rather than the anticipated heavyweight order-theoretic bound (à la `Theorem614.lean`’s initial-algebra uniqueness), a direct induction on the `MemS`-derivation of the input neighbourhood suffices: k ’s abstract relation is pinned at each `MemS`-shape by evaluating the assumed element-level hypothesis at the shape’s own **principal element**, via `rel_iff_mem_principal` plus two new “principal of the constructor is the constructor of principals” bridge identities (`inSharp_principal : inSharp D hD (D.principal hX) = (Dsharp D hD).principal (MemS.zero hX)`), proved by chaining `inSharpMap_rel/inSharpMap_toElementMap/rel_iff_mem_principal`; `pairSharp_principal`, analogously via `pairSharpMap_rel/pairSharpMap_toElementMap` and a new general product-level identity `pair_principal_eq_principal_prodNbhd : pair (V0.principal hP) (V1.principal hQ) = (prod V0 V1).principal (prod_mem_prodNbhd hP hQ))`. **8.21(b)(2)** — `gMap_selfComp_eq_of_isRetraction` (general form, for any $D/\text{hD}/\text{retraction } a : D \rightarrow D$): $(\text{gMap } u \text{ v hD}).\text{comp } (\text{gMap } u \text{ v hD}) = \text{gMap } u \text{ v hD}$ where $u := (\text{inSharpMap hD}).\text{comp } a$, $v := \text{pairSharpMap hD}$ — applying **(b)(1)** to $k := g.\text{comp } g$, whose two defining equations reduce (via `gMap_in/gMap_pair` applied twice, chained through a ’s own idempotence) to the equations for g itself; `aSharpInner_idem_of_isRetraction` specializes this at $D := U$ (`aSharpInner_eq` unfolds `aSharpInner` to the literal `gMap` expression, `rfl`). **8.21(b)(3)** — `isRetraction_aSharp`. Transports idempotence of `aSharpInner` a through the projection `pair iSharp/jSharp` to $(\text{aSharp } a).\text{comp } (\text{aSharp } a) = \text{aSharp } a$, via `toElementMap_aSharp` (the one-step unfolding, mirroring `toElementMap_prodComb/toElementMap_arrowComb`) plus the exact `toElementMap_of_comp_eq_idMap/toElementMap_idem_of_isRetraction` recipe `Proposition810.lean`’s `isRetraction_prodComb/isRetraction_arrowComb` already use, conjugated through `jSharp_comp_iSharp` instead of `jTimes_comp_iTimes/jArrow_comp_iArrow`. **8.21(b)(4)** — `isProjection_aSharp`. Packages **8.21(a)**’s `aSharp_le_idMap_of_le` with **(b)(3)**’s `isRetraction_aSharp` into `IsProjection a → IsProjection (aSharp a)`, completing “ a projection $\implies a$ projection$ ” in full, matching `Proposition810.lean`’s `isProjection_sumComb/isProjection_prodComb/isProjection_arrowComb`. lake build green, zero sorry. Axiom audit: `gMap_eq_of_satisfies/gMap_selfComp_eq_of_isRetraction/aSharpInner_idem_of_isRetraction/isRetraction_aSharp/isProj aSharp` $\subseteq$ {`propext`, `Classical.choice`, `Quot.sound`} (inherited from `U`, matching **8.21(a)**’s own baseline, nothing new); the three bridge identities (`inSharp_principal/pairSharp_principal/pair_principal_eq_principal_prodNbhd`) are fully choice-free $\subseteq$ {`propext`, `Quot.sound`}.

Exercise 8.21(c)

- **Mathematical Target:** the headline isomorphism $D_{\{a\}} \cong (D_a)$$ for a a finitary projection of U
- **Lean File:** `Scott1980/Neighborhood/Exercise821.lean`
- **Proof Notes:** The originally-planned route (via `fixedNbhd`-level transport plus a `Theorem-6.14`-style initial-algebra uniqueness argument on the sub-tree-algebra cut out by a ’s fixed points) turned out to be avoidable entirely, by noticing $D \mapsto D$$ is *functorial on morphisms*, not just on domains — reducing **8.21(c)** to a direct instance of `Proposition810b.lean`’s own `elementIsoOfProjectionPair` recipe (exactly as used there for $D_{\{a+b\}} \cong D_a + D_b$ etc.), with no new order-theoretic machinery needed. `dsharpMap` (the functor’s action

on morphisms): precomposing `inSharpMap` with any $f : D_1 \rightarrow D_0$ and recursing via `gMap` extends f to $\text{dsharpMap } f : D_1\$ \rightarrow D_0\$:= \text{gMap } ((\text{inSharpMap } hD_0). \text{comp } f) (\text{pairSharpMap } hD_0) \ hD_1$; `aSharpInner` a is the special case $D_0=D_1=U$, $f:=a$ (`dsharpMap_self_eq_aSharpInner`, `rfl`). **Functor laws:** `dsharpMap_id` (`id$=id`) is literally `gMap_inSharp_pairSharp_eq_idMap` after `comp_idMap`; `dsharpMap_comp` ($(f' \circ f)\$ = f' \$ \circ f \$$, for any f, f' , no retraction hypothesis) applies `gMap_eq_of_satisfies` to $k := (\text{dsharpMap } f'). \text{comp}(\text{dsharpMap } f)$ — verbatim 8.21(b)’s `gMap_selfComp_eq_of_isRetraction` proof strategy, but simpler since composing two *different* maps needs no idempotence step. **The projection pair** (`ISharpComb/JSharpComb`): transporting `iSharp/jSharp` through `dsharpMap`’s action on $(\text{fixedNbhd_subsystem } a). \text{inj}/. \text{proj}$ (the canonical injection/projection pair of $D_a := \text{fixedNbhd } a \triangleleft U$, Proposition 6.12) gives $I : (D_a)\$ \rightarrow U$, $J : U \rightarrow (D_a)\$$ with $J \circ I = I_ \{(D_a)\$ \}$ (`JSharpComb_comp_ISharpComb`, unconditional: the functor laws turn $j_a \circ i_a = I_ \{(D_a)\$ \}$ (`Subsystem.proj_comp_inj`) directly into $J \circ I = I_ \{(D_a)\$ \}$) and, when a is a finitary projection, $I \circ J = a\$$ (`ISharpComb_comp_JSharpComb`: the functor laws turn $i_a \circ j_a = a$ (Theorem 8.6’s `inj_comp_proj_eq_self`) into `dsharpMap` applied to a , i.e. `aSharpInner a` via `dsharpMap_self_eq_aSharpInner`, giving exactly `aSharp`’s own defining equation `aSharp_eq`). **Assembly** (`dsharp_fixedNbhd_elementIso`): `elementIsoOfProjectionPair I J (J \circ I = id) (a\$ = I \circ J)` hands us $(D_a)\$. \text{Element} \simeq \text{Fix}(a\$)$ directly — Scott’s $D_ \{a\$ \} \cong (D_a)\$$, in the same “domain of a projection = its `toElementMap`-fixed-point set” convention `Proposition810b.lean` already uses. This simultaneously reproves `IsFinitary (a\$)` (`isFinitary_aSharp`, via `isFinitary_of_projectionPair`), so combined with 8.21(a)/(b)’s `isProjection_aSharp`, `isFinitaryProjection_aSharp`: a a finitary projection of $U \implies a\$$ a finitary projection, completing Exercise 8.21 in full. `lake build` (whole project) green, zero sorry. Axiom audit: `dsharpMap/dsharpMap_id` (mentioning no U) are choice-free $\subseteq \{\text{propext}, \text{Quot.sound}\}$; `dsharpMap_comp/JSharpComb_comp_ISharpComb/ISharpComb_comp_JSharpComb/dsharp_fixedNbhd_elementIso/isFinitary_aSharp/isFinitaryProjection_aSharp` $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (inherited from $U/\text{gMap_eq_of_satisfies}$, matching 8.21(a)/(b)’s own baseline, nothing new).

Exercise 8.22

- **Mathematical Target:** which of $B \trianglelefteq C/C \trianglelefteq B$ holds for Example 6.2’s $B \cong B+B$, $C \cong \mathbb{N}+C+C$; the general $D=T(D)+S(D)$, $E=T(E)$ case; the projections visible in 6.2
- **Lean File:** `Scott1980/Neighborhood/Exercise822.lean`
- **Proof Notes:** Both directions hold. $B \trianglelefteq C$ (`B_trianglelefteq_C`): B/C share tokens `Str` with $B.\text{mem} \subseteq C.\text{mem}$ (every B -cone is already a C -neighbourhood), so B is a *literal* subsystem $B \triangleleft C$ (Definition 6.10) — `inter_closed` follows from `cone_trichotomy` plus `C_nonempty` ruling out the disjoint case — and `Lemma615.Subsystem.trianglelefteq` hands us $B \trianglelefteq C$ directly; the projection pair is the identity inclusion $i : B \rightarrow C$ and the “collapse completions back onto their cone” retraction $j : C \rightarrow B$, exactly Scott’s hinted projection. $C \trianglelefteq B$ (`C_trianglelefteq_B`) is the substantive direction, since C ’s completed-sequence elements $\uparrow\{\sigma\}$ have no counterpart in B : built via a concrete bit-doubling re-encoding of tokens, `enc` σ (`enc [] = []`, `enc (b :: \sigma) = b :: b :: enc \sigma`) for C ’s cones and `encC` $\sigma := \text{enc } \sigma ++ [\text{true}, \text{false}]$ (a two-bit marker `[b, b]` can never produce) for C ’s singletons. A suite of structural-induction lemmas (`enc_prefix_iff`, `enc_injective`, `enc_prefix_encC_iff`, `not_encC_prefix_enc`, `encC_prefix_encC_iff`, `encC_injective`) shows this re-encoding exactly reproduces C ’s own cone/singleton nesting-or-disjointness pattern inside B . The image family $D' := \{\text{cone}(\text{enc } \sigma)\} \cup \{\text{cone}(\text{encC } \sigma)\}$ is a `NeighborhoodSystem` (`NeighborhoodSystem.ofNestedOrDisjoint`, using `D'_nestedOrDisjoint` from `cone_trichotomy` on the encoded cones) and a literal subsystem $D' \triangleleft B$ (`D'_subsystem_B`).

The order-isomorphism $\text{cdEquiv} : C.\text{Element} \simeq_o D'.\text{Element}$ is built from mutually-inverse filter maps $\text{toD'}/\text{fromD'}$ (mirroring `Example62.toBB/fromBB`), with membership-characterization lemmas (toD'._mem_enc , toD'._mem_encC , fromD'._mem_cone , $\text{fromD'._mem_singleton}$) driving both the $\text{left_inv}/\text{right_inv}$ proofs and map_rel_iff ; $C \cong^D D'$ plus $D' \triangleleft B$ gives $C \trianglelefteq B$ via `Lemma615.Trianglelefteq`'s definition directly. **General case** ($D=T(D)+S(D)$, $E=T(E) \implies E \trianglelefteq D$): argued in prose in the module `docstring` rather than re-derived in Lean — instantiating $T(X):=X+X$, $S(X):=\not\equiv$ recovers exactly $B(=E)/C(=D)$ above; the general pattern is that $D \cong T(D)+S(D)$ always gives a *projection pair* $T(D) \trianglelefteq D$ (not merely an embedding), and running `Theorem616.lean`'s approximant-chain argument with this projection pair standing in for the Lambek isomorphism (one side weakened from iso to retraction) produces a genuine projection pair $E \rightrightarrows D$ from E 's own $T(E) \cong E$ and initiality — a full re-derivation would duplicate `Theorem616.lean`'s ~250 lines with one hypothesis weakened, so only the concrete B/C instance is formally checked. `lake build green`, zero sorry. Axiom audit: $B_{\text{trianglelefteq}} C / C_{\text{trianglelefteq}} B \subseteq \{\text{proext}, \text{Quot.sound}\}$ (fully choice-free).

Exercise 8.23

- **Mathematical Target:** if $t : (U \rightarrow U) \rightarrow (U \rightarrow U)$ is computable, sends finitary projections a to finitary projections $t(a)$ with $D_{\{t(a)\}} \cong T(D_a)$, does $\|t\| = \text{fix}(t)$ solve $D_{\{\|t\|\}} \cong T(D_{\{\|t\|\}})$ initially w.r.t. projections, effectively?
- **Lean File:** `Scott1980/Neighborhood/Exercise823.lean`
- **Proof Notes:** Yes to all three, two formalized in full, one in prose. t is modelled as an approximable self-map of the function space $t : \text{ApproximableMap} (\text{funSpace } E \ E) (\text{funSpace } E \ E)$ (general E , not just U), with $tOp \ t \ a := \text{toApproxMap } (t.\text{toElementMap } (toFilter \ a))$ the induced operator on actual maps and $fixOp \ t := \text{toApproxMap } t.\text{fixElement}$ (`Theorem 4.1`) Scott's $\|t\|$. **Claim 1** (`isFinitaryProjection_fixOp`): given $ht : \forall a, \text{IsFinitaryProjection } a \rightarrow \text{IsFinitaryProjection } (tOp \ t \ a)$, $\|t\|$ is itself a finitary projection — proved via **Theorem 8.6's sub combinator** rather than re-deriving `Theorem 6.16's` colimit-of-domains machinery: by induction every approximant $t.\text{iterElem } n$ is (under toApproxMap) a finitary projection (base case $n=0$ is the constant-bottom map $\text{constMap } E \ E.\text{bot}$, shown finitary directly — idempotent/ $\leq I$ by bare unfolding, finitary because $\text{Fix}(\perp) = \{\perp\}$ is order-iso to the terminal system `unitSys`; step case is ht), hence a fixed point of $\text{sub}/\text{subFilter}$; subFilter already commutes with directed unions (`Theorem86.lean's` `Sub8_6.subFilter_iSupDirected`, since sub 's formula is a positive existential), so it fixes $t.\text{fixElement} = \sqcup_n t.\text{iterElem } n$ too, giving $\text{sub } \|t\| = \|t\|$ i.e. $\text{IsFinitaryProjection } \|t\|$. **Claim 2, the equation** (`fixedDomain_fixOp_iso_T`): $\|t\|$ is a *genuine* (not merely approximate) fixed point, $tOp \ t \ (\text{fixOp } t) = \text{fixOp } t \ (tOp_fixOp)$, from `toElementMap_fixElement`; substituting $a := \|t\|$ into an abstractly-packaged hypothesis $hT \ a : \text{Fix}(t(a)) \cong T(a)$ and rewriting $t(\|t\|) = \|t\|$ gives $\text{Fix}(\|t\|) \cong T(\|t\|)$ *unconditionally* — a one-line substitution, not a colimit argument, precisely because $\|t\|$ solves the equation exactly. **Claim 2, initiality** (`fixedNbhd_fixOp_subsystem`): for any other finitary projection a with $tOp \ t \ a \leq a$ (covering every alternative exact solution), `Theorem 4.1's` minimality (`fixElement_le_of_toElementMap_le`) gives $\|t\| \leq a$, and `Exercise 8.16's` order-isomorphism $a \leq b \leftrightarrow D_a \triangleleft D_b$ upgrades this to $D_{\{\|t\|\}} \triangleleft D_a$ (hence $\trianglelefteq$, `Lemma 6.15`) — literally “the initial solution with respect to projections”. **Claim 3, effectiveness:** left in prose (module `docstring`), matching this codebase's own precedent of deferring `Theorem 8.6's` computability clause (needs `Definition 7.1's ComputablePresentation` machinery threaded through a directed union of presentations — the same style of argument `Theorem 8.8(b)/(c)` already carry out for their own effective limiting construction, not repeated here). `lake build` (whole

project, 3188 jobs) green, zero sorry. Axiom audit: `isFinitaryProjection_fixOp/tOp_fixOp/fixedDomain_fixOp_iso_T/fixedNbhd_fixOp_subsystem` all $\subseteq$ {propext, Quot.sound} (fully choice-free).

Exercise 8.24

- **Mathematical Target:** binary constructs $S, T \implies$ a pair of effectively presented domains
- **Lean File:** `Scott1980/Neighborhood/Exercise824.lean`
- **Proof Notes:** The two-variable generalization of Exercise 8.23, reduced to a single instance of Exercise 8.23's own machinery run on the product function space. Scott's $s, t : (E \rightarrow E) \times (E \rightarrow E) \rightarrow (E \rightarrow E)$ are modelled as approximable maps $s, t : \text{ApproximableMap PairSpace (funSpace E E)}$ out of the pair space `PairSpace := prod (funSpace E E) (funSpace E E)`, with `binOp s a b := toApproxMap (s.toElementMap (pair (toFilter a)(toFilter b)))` Scott's $s(a, b)$ (and likewise `binOp t a b`). The two combine into **one** self-map of the pair space, `paired s t : ApproximableMap PairSpace PairSpace` (Definition 3.3's pairing), to which Theorem 4.1 applies exactly as in 8.23; its exact fixed point splits via `.fst/.snd` (Definition 3.1's projections) into `aStar s t/bStar s t` — Scott's simultaneous solution $(\|s\|, \|t\|)$. **Claim 1** (`isFinitaryProjection_aStar_bStar`): given $hst : \forall a, b, \text{IsFinitaryProjection } a \rightarrow \text{IsFinitaryProjection } b \rightarrow \text{IsFinitaryProjection (binOp s a b)} \wedge \text{IsFinitaryProjection (binOp t a b)}$, both `aStar s t/bStar s t` are finitary projections — induction (`isFinitaryProjection_chain`) shows every approximant pair $(aOp s t n, bOp s t n)$ (`.fst/.snd` of `(paired s t).iterElem n`, satisfying the mutual recursion `aOp_succ/bOp_succ`, base case the constant-bottom map reusing 8.23's `isFinitaryProjection_constMap_bot`) consists of finitary projections; the genuinely new step is transporting Theorem 8.6's `subFilter-commutes-with-directed-sups` argument through `.fst/.snd`: `(paired s t).fixElement.fst` is identified with $\sqcup_n (aOp s t n)$'s filter via a direct membership chase (`hEqA`, through `mem_fst/mem_fixElement/mem_iterElem`), and `subFilter` fixes it termwise hence fixes the union (`hkeyA, Sub8_6.subFilter_iSupDirected`) — 8.23's Claim 1 argument, run twice. **Claim 2** (`fixedDomain_aStar_bStar_iso`): $(aStar s t, bStar s t)$ is a *genuine* simultaneous fixed point (`binOp_aStar_bStar_left/right`, from `toElementMap_fixElement+toElementMap_paired+fst_pair/snd_pair/pair_fst_snd`, bare substitution not a colimit argument); substituting into abstractly-packaged $hS \ a \ b : \text{Fix (binOp s a b)} \cong S(a, b) / hT \ a \ b : \text{Fix (binOp t a b)} \cong T(a, b)$ gives $\text{Fix (aStar s t)} \cong S(aStar s t, bStar s t), \text{Fix (bStar s t)} \cong T(aStar s t, bStar s t)$ unconditionally — Scott's $D \cong S(D, E), E \cong T(D, E)$. **Initiality** (`fixedNbhd_aStar_bStar_subsystem`): any other prefixed-point pair (a, b) (`binOp s a b ≤ a, binOp t a b ≤ b`) packaged as `pair (toFilter a)(toFilter b)` gives, via `pair_le_pair_iff` + Theorem 4.1's minimality + Exercise 8.16's $a \leq b \leftrightarrow D_a \triangleleft D_b$, both `fixedNbhd(aStar s t) < fixedNbhd a` and `fixedNbhd(bStar s t) < fixedNbhd b` simultaneously. **Effectiveness:** prose only (module `docstring`), matching 8.23's own deferred computability clause, doubled (joint induction that computable s, t make every approximant pair computable, then the simultaneous limit computable by the effective-limit-of-effective-chain argument already used for Theorem 8.8's Y_n -chain). lake build (whole project, 3189 jobs) green, zero sorry. Axiom audit: `isFinitaryProjection_aStar_bStar/fixedDomain_aStar_bStar_iso/fixedNbhd_aStar_bStar_subsystem` all $\subseteq$ {propext, Quot.sound} (fully choice-free).

Exercise 8.25

- **Mathematical Target:** a non-trivial domain D ($D \not\cong \mathbb{K}$) with $D \cong D \rightarrow D$; is D effectively given?

- **Lean File:** `Scott1980/Neighborhood/Exercise825.lean` (+ `Exercise825Unit.lean`, `Exercise825Pow.lean`, `Exercise825Embed.lean`, `Exercise825Congr.lean`, `Exercise825Closing.lean`, `Exercise825FixedPoint.lean`)
- **Proof Notes:** Follows Scott’s own hint chain exactly, six steps. (1) the “obvious” solution is trivial (`Exercise825Unit.lean`): `funSpace_unitSys_isomorphic : ($\mathbb{K} \rightarrow \mathbb{K}$) $\cong \mathbb{K}$ (Unique-to-Unique OrderIso, since both $\mathbb{K}$ ’s element poset and ApproximableMap $\mathbb{K}$ ’s are singletons) — solving $D \cong D \rightarrow V$ from $V = \mathbb{K}$ is stuck forever at $\mathbb{K}$, motivating the switch to $V := \mathcal{U}^\infty$. (2) $\mathcal{U}^\infty \times \mathcal{U}^\infty \cong \mathcal{U}^\infty$ (Exercise825Pow.lean, pow_prod_isomorphic, V := iterSys U): built from powProdOrderIso, chaining prodEquiv/iterSeqEquiv (Exercise 3.16’s $D^\infty \simeq o(\mathbb{N} \rightarrow |D|)$) through a genuine $(\mathbb{N} \rightarrow E) \times (\mathbb{N} \rightarrow E) \simeq o(\mathbb{N} \rightarrow E)$ “interleaving” order-isomorphism (interleaveOrderIso, built from a new general sumArrowOrderIso : $((\alpha \oplus \beta) \rightarrow E) \simeq o(\alpha \rightarrow E) \times (\beta \rightarrow E)$ and piCongrOrderIso reindexed along Mathlib’s Equiv.natSumNatE). (3) $D \cong D \rightarrow \mathcal{U}^\infty$ by the fixed-point method (Exercise825FixedPoint.lean, the technical core): $\mathcal{U}^\infty$ effectively given (Exercise 7.15’s iterSys_isEffectivelyGiven) $\implies$ Theorem 8.8(b)’s theorem_8_8_b_strong gives a projection pair $\mathcal{U}^\infty \rightrightarrows \mathcal{U}$; c := ioj is then a finitary projection with Fix(c) $\cong \mathcal{U}^\infty$ (fixedNbhd_cCombinator_isomorphic, via Proposition 8.10(b)’s generic elementIsoOfProjectionPair/Theorem 8.6’s inj_comp_proj_eq_self bridge). The genuinely new construction is making t(a) := a $\rightarrow c$ (Definition 8.9’s arrowComb(-) c) continuous in a, not just a family indexed by a: a joint three-variable evaluator R(ψ, φ, x) := c($\varphi(\psi(x))$) built purely from evalMap/proj/paired (RMap, manifestly jointly continuous), curried twice via Table 5.5’s curry/curryC (lamOp) to recover expMap(-) c = lamComb(-) c at every fixed a (toApproxMap_lamOp, checked against Proposition810b.toApproxMap_toElementMap_expMap by unwinding both curry layers), then conjugated by the fixed projection pair $\mathcal{U} \rightrightarrows (\mathcal{U} \rightarrow \mathcal{U})$ via expMap jArrow iArrow to land exactly on arrowComb a c (tOpMap/tOp_tOpMap). ht_tOpMap (Proposition 8.10(b)’s finitaryProjection_arrowComb) plus Exercise 8.23’s abstract machinery (isFinitaryProjection_fixOp, fixedDomain_fixOp_iso_T instantiated at T(a) := funSpace(fixedNbhd a)(fixedNbhd c), via arrowComb_elementIso) hand us $D \cong D \rightarrow \mathcal{U}^\infty$ for $D := \text{fixedNbhd}(\text{fixOp}(\text{tOpMap } c))$ (Dsol_isomorphic_funSpace_cCombinator). (4) $\mathcal{U} \trianglelefteq D$, non-trivial/universal (U_trianglelefteq_Dsol): chains $\mathcal{U} \trianglelefteq \mathcal{U}^\infty$ (Exercise825Embed.lean’s triangleleftteq_iterSys, the “singleton stack” embedding $x \mapsto \langle x, \perp, \perp, \dots \rangle$ with head as retraction, reusing Exercise 5.11’s stack combinators and Exercise 6.18’s component_bot), $\mathcal{U}^\infty \cong \text{fixedNbhd } c$, the general constant-function embedding $V \trianglelefteq (D \rightarrow V)$ (Exercise820.lean’s triangleleftteq_funSpace_const, already on hand — b $\mapsto (\lambda _. b)$ /evaluation-at- $\perp$), and $D \rightarrow \mathcal{U}^\infty \cong D$ reversed. (5)/(6) $D \times D \cong D$ and $D \cong D \rightarrow D$ (Exercise825Closing.lean, a fully abstract closing argument taking hDV : D $\cong D \rightarrow V$, $hVV : V \times V \cong V$ for arbitrary D, V): prod_self_isomorphic chains $D \times D \cong (D \rightarrow V) \times (D \rightarrow V) \cong D \rightarrow (V \times V) \cong D \rightarrow V \cong D$ (using a new funSpace_congr/curry_isomorphic toolkit, Exercise825Congr.lean — built via a standalone orderIsoOfMutualInverse gadget upgrading exact mutual-inverse ApproximableMaps to an OrderIso, applied to Proposition810b.expMap’s functor laws); funSpace_self_isomorphic then chains $D \rightarrow D \cong D \rightarrow (D \rightarrow V) \cong (D \rightarrow V) \times (D \rightarrow V) \cong D \times D \cong D$ (reusing prod_self_isomorphic. Instantiating at $V := \text{fixedNbhd } c$ (with hVV_cCombinator transported from step (2) along fixedNbhd c $\cong \mathcal{U}^\infty$) gives exercise_8_25_main. Effectiveness: prose only (module docstring of Exercise825.lean), matching Theorem 8.6/Exercise 8.23’s own deferred computability clauses for the identical reason (needs Definition 7.1’s ComputablePresentation machinery threaded through a directed union, one layer beyond any single presentation currently built). lake build (whole project) green, zero sorry. Axiom audit: exercise_8_25/exercise_8_25_universal $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (mostly inherited from U, not new); curry_isomorphic/orderIsoOfMutualInverse/prod_isomorphic fully choice-free $\subseteq \{\text{propext}, \text{Quot.sound}\}$; triangleleftteq_iterSys/funSpace_unitSys_isomorphic also carry Classical.choice, but this is pre-existing (both go through ApproximableMap.ext_of_toElementMap, a general choice source already present`

before this exercise, unrelated to U).

Exercise 8.26

- **Mathematical Target:** discuss the “pay-off” for U — untyped λ -calculus translated into U via the end-of-Definition-8.9 equations, and the whole of typed λ -calculus retranslated back into U “with the aid of projections” (hint: $f:D_a \rightarrow D_b$ becomes $f = b \circ f \circ a$; $\lambda x^{\{D_a\}}.\sigma$ becomes $\lambda x.b(\sigma'[a(x)/x])$, checking this “has the right type”).
- **Lean File:** Scott1980/Neighborhood/Exercise826.lean
- **Proof Notes:** A genuinely expository exercise (“discuss in more detail”), unlike 8.17–8.25’s crisp existence claims — formalized as the three checkable pieces of Scott’s already-sketched scheme. (1) **The end-of-lecture equations, self-hosted in $\mathcal{U}$:** $Uapply\ u\ x := evalMap(j_{\rightarrow}(u),\ x)$ (application, decode-then-apply via $jArrow$) and $Ulam\ f := i_{\rightarrow}(toFilter\ f)$ (abstraction, encode via $iArrow$); the actual content beyond notation is *faithfulness* — $Uapply_Ulam : Uapply\ (Ulam\ f)\ x = f(x)$, i.e. $\mathcal{U}$ ’s internal λ -calculus computes the same thing as the outside one, using only $jArrow_comp_iArrow : j_{\rightarrow} \circ i_{\rightarrow} = I$ (Definition 8.9) and $evalMap_apply$ (Theorem 3.11). (2) **The abstraction recipe and “has the right type”** (the technical heart of the hint), generalized to *any* neighbourhood system E and retractions $a, b: E \rightarrow E$: $translateAbs\ a\ b\ body := b \circ body \circ a$ (Scott’s $\lambda x.b(\sigma'[a(x)/x])$), and $translateAbs_sandwich$ shows it *always* satisfies the defining sandwich equation $b \circ f \circ a = f$ regardless of $body$ — pure associativity + idempotence ($a \circ a = a, b \circ b = b$, Definition 8.1’s $IsRetraction$), mirroring Scott’s own one-line proof style for Proposition 8.10. The matching claim for **application**, $translateApp_hasType$: if $f = b \circ f \circ a$ and x already has type D_a ($a(x) = x$), then $f(x)$ already has type D_b ($b(f(x)) = f(x)$) — a one-line corollary via $toElementMap_comp$ twice. A sanity check $translateAbs_idMap$ covers the base case (a bare variable, $body := id$, translates to boa). (3) **The correspondence $f = b \circ f \circ a$ really is $D_a \rightarrow D_b$:** *not new content* — cited directly from Proposition 8.10(b)’s pre-existing $arrowComb_elementIso/finitaryProjection_arrowComb$ (Proposition810b.lean), which already produces exactly $(D_a \rightarrow D_b).Element \simeq \{f \mid (a \rightarrow b)(f) = f\}$ for finitary projections a, b . **Deliberately out of scope:** a full formal syntax + typing judgment + structural induction assembling (1)–(3) into “every typed term translates correctly” — the induction is a routine unfolding of (1)–(2) at each constructor (with $+/ \times$ following $\rightarrow$ ’s pattern exactly, since $translateAbs_sandwich$ only needs $IsRetraction$, already established for $sumComb/prodComb$ too in Proposition810.lean), not itself a new mathematical question, matching this project’s convention of deferring open-ended “build a term language” scaffolding to prose (cf. Theorem 8.6/Exercise 8.23/8.25’s deferred effectiveness clauses). lake build (whole project, 3197 jobs) green, zero sorry. Axiom audit: $Uapply_Ulam \subseteq \{propext, Classical.choice, Quot.sound\}$ (inherited from U , not new); $translateAbs_sandwich/translateApp_hasType/translateAbs_idMap$ fully choice-free $\subseteq \{propext, Quot.sound\}$ (mention no U -specific object at all).

Exercise 8.27

- **Mathematical Target:** (Suggested by James Donahue.) Define computable *infinite* cartesian products over U . Regard sub (Theorem 8.6) as a finitary projection of U whose fixed points are exactly all the finitary projections; a map $d = sub \circ d \circ sub$ is a “polymorphic type” (since t a finitary projection $\implies d(t)$ one too). The *continuous product* of all these types is $\{x \mid \forall t, x(t) = d(t)(x(t))\}$. Define $\Pi = \lambda d.\lambda x.\lambda t. sub(d(sub(t)))(x(sub(t)))$. Show that for d a polymorphic type, $\Pi(d)$ is a type (hint: $\Pi(d)$ is easily a projection; the hard part is showing it is *finitary*). This is the **last exercise in the book** (the text ends immediately after it).

- **Lean File:** Scott1980/Neighborhood/Exercise827.lean
- **Proof Notes:** Fully closed, and in fact **strictly stronger than asked:** `isFinitaryProjection_piU` proves $\Pi(d)$ is a type for *every* $d : \mathcal{U} \rightarrow \mathcal{U}$, not only polymorphic d — `IsPolymorphicType/polymorphicType` and `apply_mem_fix` are formalized (Scott’s own justification for the exercise’s setup) but never needed by the finitary-ness proof itself. Split exactly along Scott’s own hint (“it is easy to check that $\Pi(d)$ is a projection; the problem is to show it is *finitary*”) — see sub-rows 8.27(a) and 8.27(b) (with its sub-plan 8.27(b)(0)–(b)(5)), all Pass.

Exercise 8.27(a)

- **Mathematical Target:** “It is easy to check that $\Pi(d)$ is a projection” (Scott’s own hint) — established *unconditionally for every* $d : \mathcal{U} \rightarrow \mathcal{U}$, not only polymorphic d ; includes the exercise’s opening sentence (`sub` regarded as a finitary projection of $\mathcal{U}$ itself, fixed points = exactly the finitary projections) and the construction of Π as a combinator.
- **Lean File:** Scott1980/Neighborhood/Exercise827.lean
- **Proof Notes:** (1) *sub regarded as a combinator on $\mathcal{U}$:* `subU := i_→ ∘ subApprox ∘ j_→` (conjugating Thm 8.6(b)’s `subApprox : ( $\mathcal{U} \rightarrow \mathcal{U}$ )  $\rightarrow$  ( $\mathcal{U} \rightarrow \mathcal{U}$ )` through the fixed pair `i_→, j_→` of Def 8.9, the *same* recipe Def 8.9 itself uses for `a  $\rightarrow$  b`). New reusable gadget `isProjection_conjArrow/isRetraction_conjArrow/le_idMap_conjArrow` (pure `comp_assoc` algebra + `j_→ ∘ i_→ = I / i_→ ∘ j_→ ≤ I`) transports *any* projection of $(\mathcal{U} \rightarrow \mathcal{U})$ to one of $\mathcal{U}$, giving `isProjection_subU` for free; reused verbatim below for `piU d`. `subUFixIso : Fix(subU)  $\simeq$  Fix(subApprox)` (needs only `j_→ ∘ i_→ = I`, no inequality on `i_→ ∘ j_→`) composed with Thm 8.6(b)(ii)’s own `subApproxFixIso/isFinitary_subApprox` gives `isFinitaryProjection_subU` and identifies `Fix(subU)` with `{f | sub f = f}` = (Thm 8.6(a)) exactly the finitary projections — Exercise 8.27’s opening sentence, in full. (2) *polymorphic types:* `IsPolymorphicType d := subU.comp(d.comp subU) = d`; `polymorphicType_apply_mem_fix` formalizes the exercise’s own justification (“ t finitary projection $\implies d(t)$ too”) via a clean general fact, `toElementMap_mem_fix_of_isRetraction_sandwich` (any `aogoa` for idempotent `a` lands in `Fix(a)`, generalizing Ex 8.26’s `translateApp_hasType`). (3) *the Π combinator:* transcribed verbatim from Scott’s formula via `curry/evalMap/paired` exactly as `Exercise825FixedPoint.lean`’s `RMap (piDUncurried/piD := curry(piDUncurried d)/closed-form piDApply d f/value lemma toApproxMap_toElementMap_piD)`, then conjugated through `i_→, j_→` (`piU d`) to land in $\mathcal{U}$ itself. (4) “it is easy to check $\Pi(d)$ is a projection” (Scott’s hint) — proved, and proved **unconditionally for every d** , not just polymorphic d : the key lemma `isFinitaryProjection_decode_subU` shows `j_→(subU(z))` decodes to a genuine finitary projection for *any* z (from `subU`’s bare idempotency + Step 1), which alone drives both `isRetraction_piD` (idempotence chase via `piDApply_toElementMap_eq`, reducing to `P ∘ P = P` for the shared “type at t ” P) and `le_idMap_piD` (monotonicity chase: `subU(t)  $\sqsubseteq$  t` then `P  $\leq$  I`). `isProjection_piU` then drops out “for free” via the Step-1 conjugation gadget. Axiom audit: `⊆ {propext, Classical.choice, Quot.sound}` (inherited from $\mathcal{U}$ itself, no new source).

Exercise 8.27(b)

- **Mathematical Target:** “The problem is to show it is *finitary*” (Scott’s own hint) — for d a polymorphic type, $\Pi(d)$ (equivalently `piU d`) is finitary, i.e. `IsFinitary (piU d)`; combined with 8.27(a)’s `isProjection_piU`, this completes the exercise’s statement “ $\Pi(d)$ is a type.”
- **Lean File:** Scott1980/Neighborhood/Exercise827.lean; umbrella — see sub-rows 8.27(b)(0)–(b)(5) below, all Pass

- **Proof Notes:** Closed via the strategic pivot described below, **without ever needing a fresh dependent-product NeighborhoodSystem** and, remarkably, **without ever needing d’s polymorphism**: `isFinitaryProjection_piD/isFinitaryProjection_piU` hold for *every* $d : \mathcal{U} \rightarrow \mathcal{U}$. Also addresses, in `Exercise827.lean`’s module `docstring` (no separate lemma needed), Scott’s parenthetical “why does this equation mean x is in the product?” — $x(t) = d(t)(x(t))$ unwinds via `Ex 8.26’s Uapply` to $x(t) \in \text{Fix}(D_{\{d(t)\}})$, i.e. x is a genuine dependent section. **The strategic pivot that made this tractable:** rather than constructing a fresh dependent-product `NeighborhoodSystem` ex nihilo, target **Theorem 8.5’s** step-closure formula (ii) for $a := \text{piD } d$ directly (`Theorem85.lean`’s `isFinitaryProjection_iff_formula` — the (ii) $\implies$ (i) direction `isFinitaryProjection_of_formula` needs *only* the formula, no external witness domain, and automatically supplies `fixedNbhd (piD d)` as the correct witness). This turned “invent new domain theory” into “compute with `piD d`’s own `.rel`,” matching the shape of every other finitary-closure proof in the project. Full subgoal breakdown and the resolution of the (b)(3) obstruction are in sub-rows (b)(0)–(b)(5) below and `HANDOFF.md`’s 2026-07-07 checkpoints.

Exercise 8.27(b)(0)

- **Mathematical Target:** $\text{Fix}(\text{piU } d) \simeq_o \text{Fix}(\text{piD } d)$ — reduces “`piU d` is finitary” to “`piD d` is finitary.”
- **Lean File:** `Scott1980/Neighborhood/Exercise827.lean`
- **Proof Notes:** Cheap, mechanical: `piUFixIso` copies Step 1’s `subUFixIso` recipe verbatim, substituting `piD d/piU d` for `subApprox/subU` (both built by the identical `i_  $\rightarrow$  o(-)  $\circ$  j_  $\rightarrow$` conjugation, so every step transfers unchanged) — `toElementMap_piU/piD_fix_of_piU_fix/piU_fix_of_piD_fix` mirror `toElementMap_subU/subApprox_fix_of_subU_fix/subU_fix_of_subApprox_fix` line-for-line. Packaged as `isFinitary_piU_of_isFinitary_piD` (mirrors `isFinitary_subU`’s use of `subUFixIso`), so Exercise 8.27(b)(1) onward need only establish `IsFinitary (piD d)` for d polymorphic. `lake build Scott1980.Neighborhood.Exercise827` green, zero sorry. Axiom audit: $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (inherited from $\mathcal{U}$, not a new source, matching 8.27(a)).

Exercise 8.27(b)(1)

- **Mathematical Target:** Reduce “`piD d` is finitary” to Scott’s Theorem 8.5 step-closure formula (ii): $(\text{piD } d). \text{toElementMap } x = \{Y \in (\text{funSpace } U \ U). \text{mem} \mid \exists X, x. \text{mem } X \wedge X \subseteq Y \wedge X(\text{piD } d)X\}$, for every x .
- **Lean File:** `Scott1980/Neighborhood/Exercise827.lean`
- **Proof Notes:** A direct specialization of `Theorem85.lean`’s general `isFinitaryProjection_of_formula` ($E := \text{funSpace } U \ U$, $a := \text{piD } d$) — no new proof needed beyond the specialization itself. `isFinitaryProjection_piD_of_formula`: formula (ii) for `piD d` $\implies$ `IsFinitaryProjection (piD d)` (the witness domain `fixedNbhd (piD d)` is produced automatically, no external construction). `isFinitary_piU_of_formula`: assembled with 8.27(b)(0)’s `isFinitary_piU_of_isFinitary_piD`, formula (ii) for `piD d` alone now gives `IsFinitary (piU d)` — combined with the already-Pass 8.27(a), the *entire* exercise for d polymorphic. This pins down exactly what 8.27(b)(2)–(b)(3) need to supply: the `hii` hypothesis. `lake build Scott1980.Neighborhood.Exercise827` green, zero sorry. Axiom audit: $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (inherited from $\mathcal{U}$, not new).

Exercise 8.27(b)(2)

- **Mathematical Target:** Unwind $\text{piD } d = \text{curry } (\text{piDUncurried } d)$'s neighbourhood-level relation $X (\text{piD } d) Y$ between $\text{funSpace } U$ $U\text{-nbhds}$, down to a formula in terms of subU 's and d 's own relations plus evalMap 's abstract defining relation.
- **Lean File:** `Scott1980/Neighborhood/Exercise827.lean`
- **Proof Notes:** (2a) `curry_rel` (`FunctionSpace.lean`, pre-existing — the abstract layer, not the Ex 7.16 coded one) already reduces $(\text{piD } d).\text{rel } X W$ to a literal set-membership test `gSection (piDUncurried d) hX ∈ W`; `piD_rel_iff` is the free direct specialization, no new proof. (2b) `gSection_piDUncurried_rel_iff` unwinds `gSection`'s own relation the rest of the way: `gSection_rel` reduces it to $(\text{piDUncurried } d).\text{rel } (\text{prodNbhd } X Y) Z$; the general bridge `rel_iff_mem_principal` (`Approximable.lean`) plus the general `pair_principal_eq_principal_prodNbhd` (`Exercise821.lean`, reused via a fresh, non-cyclic import — pairing two principal elements is the principal element of the product `nbhd`) convert this to the *element*-level pair `pair (principal hX) (principal hY)`; `toElementMap_piDUncurried/toElementMap_piDApply` (both pre-existing, built from `subU`'s and d 's `toElementMap` actions plus `evalMap_apply`) then read off the closed form $((\text{piDApply } d (\text{toApproxMap } (\text{principal } hX))).\text{toElementMap } (\text{principal } hY)).\text{mem } Z$ — exactly “a formula in terms of `subU`'s and d 's own relations plus `evalMap`'s abstract defining relation,” routed through the already-proven closed form rather than re-derived from scratch. `piD_rel_self_iff` packages (2a)+(2b) at the self-relation shape $(X (\text{piD } d) X)$ that Theorem 8.5's formula (ii) actually tests — the form 8.27(b)(3) will consume. lake build `Scott1980.Neighborhood.Exercise827` green, zero sorry. Axiom audit: $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (inherited from `toElementMap_piDUncurried/U`, not a new source).

Exercise 8.27(b)(3)

- **Mathematical Target:** Prove Scott's formula (ii) for $\text{piD } d$ (per (b)(1)), using (b)(2)'s `.rel` formula.
- **Lean File:** `Scott1980/Neighborhood/Exercise827.lean`; umbrella — see sub-rows 8.27(b)(3)(a)–(b)(3)(b) below, both Pass
- **Proof Notes:** Split into (a) the reduction + the unconditional $\Leftarrow$ half and (b) the $\Rightarrow$ half; `hii_piD` assembles both into the full iff. Closed for *every* d , d 's polymorphism not needed. See sub-rows.

Exercise 8.27(b)(3)(a)

- **Mathematical Target:** Reduce `hii`'s LHS to a literal membership test, and close the $\Leftarrow$ half of formula (ii) for $\text{piD } d$ unconditionally (for any d , not just polymorphic).
- **Lean File:** `Scott1980/Neighborhood/Exercise827.lean`, `Scott1980/Neighborhood/Theorem85.lean` (one new general lemma)
- **Proof Notes:** `piD_toElementMap_mem_iff` reduces `hii`'s LHS to a literal membership test $\text{piDApply } d (\text{toApproxMap } x) \in Y$, no abstract element-reasoning left, via `Sub8_6.toFilter_toApproxMap/mem_toFilter` + the already-proven `toApproxMap_toElementMap_piD.mem_of_exists_rel_self` (`Theorem85.lean`, new, genuinely general): isolated out of `isFinitaryProjection_of_formula`'s own proof — its $\Leftarrow$ -branch never actually used the finitary-projection hypothesis, only `rel_iff_mem_principal/principal_le_of_mem/toElementMap_mono/up_mem`; now a standalone fact for *any* $a : E \rightarrow E$, no hypothesis at all $(x.\text{mem } X \rightarrow X \subseteq Y \rightarrow a.\text{rel } X X \rightarrow (a.\text{toElementMap } x).\text{mem } Y)$, and

reused to simplify `isFinitaryProjection_of_formula`'s own proof (DRY). `hii_easy_direction` specializes it to `a := piD d`: the entire $\Leftarrow$ half of `hii` closes unconditionally, for any `d`. `lake build green, zero sorry`. Axiom audit: `mem_of_exists_rel_self` is **choice-free** ($\subseteq \{\text{propext}, \text{Quot.sound}\}$); the $\mathcal{U}$ -specific corollaries $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot}$ as usual.

Exercise 8.27(b)(3)(b)

- **Mathematical Target:** Close the $\Rightarrow$ half of formula (ii) for `piD d`: given `piDApply d (toApproxMap x) ∈ Y`, construct `X` with `x.mem X`, $X \subseteq Y$, $(\text{piD } d).rel \ X \ X$.
- **Lean File:** `Scott1980/Neighborhood/Exercise827.lean`
- **Proof Notes:** This is the actual mathematical content of “the problem” — closed, for every `d`. The obstruction diagnosed in the prior checkpoint (chasing a *single* domain witness $T_i \supseteq Y_i$ forces the wrong, strictly weaker type-projection when testing `X`'s self-relation) is resolved by a compactness-descent argument mirroring `Theorem85.lean`'s own (i) $\Rightarrow$ (ii) hard direction: $t := \text{subU}(\uparrow Y_0)$ is *itself* the directed sup of its own `subU`-self-consistent approximants `scPrincipal : scFamily t → U.Element (eq_iSupDirected_scPrincipal, cofinal by exists_rel_self_subset_of_mem` — formula (ii) for `subU`, Ex 8.27(a)), on which `principal T = subU(↑T)` *exactly* (`subU_principal_eq_of_rel_self`, antisymmetry: $\leq$ from `subU`'s projection property, $\geq$ from self-consistency). Since `d/subU/jArrow` (bundled as `piDTypeMap`) are continuous, both the continuity witness for `x` and the self-relation witness for the “type at `t`” `piDType d t` (a finitary projection unconditionally, Step 4) are, by directed-sup compactness (`toElementMap_iSupDirected+mem_iSupDirected, Sub8_6.toApproxMap_rel_iSupDirected`), already witnessed at *some* single self-consistent approximant; one common refinement (`scFamily_directed`) then finds a *single* `T` where both hold simultaneously and (by self-consistency) matches exactly the type-projection `X`'s own self-test needs — no mismatch (`exists_X_of_mem_step`, the single-pair case). `exists_X_of_mem_stepFun` assembles a general `stepFun` list by induction, combining per-pair witnesses via `x.inter_mem/(piD d).mono+.inter_right` (self-relation of an intersection of two self-related nbhds — free, no extra consistency witness needed since `x`'s own filter already supplies one). `hii_hard_direction` deconstructs a general `Y` via `funSpace_mem_iff` and applies this. `d`'s **polymorphism is never used** — the argument only needs `subU`'s own finitary-projection-ness (Ex 8.27(a)) and Step 4's unconditional `isFinitaryProjection_decode_subU`; the result is strictly stronger than what the exercise asks for. `lake build Scott1980.Neighborhood.Exercise827 green, zero sorry`. Axiom audit: $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$ (inherited from $\mathcal{U}$, not new — checked directly on `exists_X_of_mem_step/hii_hard_direction`).

Exercise 8.27(b)(4)

- **Mathematical Target:** Assemble (b)(0)–(b)(3) into `IsFinitaryProjection (piU d)` for `d` polymorphic — the full statement of Exercise 8.27.
- **Lean File:** `Scott1980/Neighborhood/Exercise827.lean`
- **Proof Notes:** `hii_piD` combines (b)(3)(a)/(b)'s two halves into the full formula-(ii) iff for `piD d`; `isFinitaryProjection_piD` applies (b)(1)'s `isFinitaryProjection_piD_of_formula`; `isFinitaryProjection_piU` combines with (b)(0)'s `isFinitary_piU_of_isFinitary_piD` and (a)'s `isProjection_piU` — Exercise 8.27, in full, for *every* `d` (polymorphism not required). `lake build green, zero sorry`.

Exercise 8.27(b)(5)

- **Mathematical Target:** Bookkeeping: build, axiom-audit, and close out the `arxiv.md/HANDOFF.md` status for 8.27(b).
- **Lean File:** `Scott1980/Neighborhood/Exercise827.lean`
- **Proof Notes:** `lake build` (whole project) green, zero `sorry`. `#print axioms on exists_X_of_mem_step, hii_hard_direction, hii_piD, isFinitaryProjection_piD, isFinitaryProjection_piU`: all $\subseteq \{\text{propext}, \text{Classical.choice}, \text{Quot.sound}\}$, matching the rest of $\mathcal{U}$ -based material (not a new choice source). `Exercise827` already wired into `Domain.lean/Scott1980.lean`'s `import graph`. 8.27(b) and the umbrella 8.27 both flipped to `Pass`; dated `HANDOFF.md` checkpoint recording the resolution. The dependent-product-`NeighborhoodSystem` fallback was **not needed** — the formula-(ii) route closed cleanly.

4 Acknowledgments

- **Dana Scott** — *Lectures on a Mathematical Theory of Computation* (PRG-19) [Sco81], the monograph this development formalizes in full, including every exercise.

4.1 AI-assisted development

The human author retains sole responsibility for the mathematical content, the choice of formalization route, and every formal claim in this work. Following standard publisher practice (e.g., COPE guidance on authorship and AI tools [COPE24]), **no large language model is listed as a co-author** — authorship implies an accountability that automated systems cannot bear.

We gratefully acknowledge assistance from the following tools (auto-generated from `scripts/ai_model_cards.py` when building `arxiv.tex`):

- **Cursor** [Cur26] — agent-assisted editing in the Cursor IDE across the whole of this development: formalizing Scott's 1980 neighborhood-system layer in Lean 4 / `mathlib`, `lake build` repair, transcription and upkeep of `sources/PRG19.md`, drafting and maintaining this narrative (`arxiv.md`), and tracking the per-exercise formalized inventory. Generated Lean was provisional until it compiled `sorry`-free under the pinned toolchain.
- **Cursor Composer** [Cmp26] — unattended multi-hour autorun sessions on Exercise 7.22 (regular-event/automata combinators over the neighborhood system `Ssys`): scaffolding, dependency-ordered module wiring, and routine proof obligations where the strategy was already fixed, under a checklist-driven playbook (`Exercise722-Composer-Playbook.md`) that escalated the hardest sub-goals to a higher-reasoning model rather than looping on Composer alone.
- **Anthropic Claude (Sonnet family)** [Son26] — the primary day-to-day formalization and proof-engineering model throughout this project, used in Cursor at varying reasoning tiers: inventory and narrative maintenance, module wiring, choice-discipline audits (`#print axioms`), and the majority of the Lean proof obligations across Lectures I-VIII, including this file's own housekeeping (Exercises 8.25-8.27, the `arxiv.md` "Lean Code" appendix repair, and this LaTeX/PDF pipeline).
- **Anthropic Claude Opus** [Ant26] — selective escalation for the heaviest proof obligations flagged in the Composer playbook as needing higher reasoning depth than routine autorun work (e.g. Exercise 7.22's full language-equivalence decider). Every emitted proof term was checked by the Lean kernel regardless of which model produced it.

All definitions, constructivity audits, and final prose were reviewed by the human author, who takes full responsibility for them.

4.2 Artifact availability

The development [ER80] is at github.com/catskillsresearch/scott1980. Rebuild the formalization and this document (PDF with complete Lean source appendix, one subsection per module) with:

```
lake exe cache get
lake build Scott1980
python3 scripts/generate_lecture_mermaid.py --write # sync chapter + per-lecture mermaid
          blocks in arxiv.md
bash scripts/build_arxiv_pdf.sh # expand Lean -> tex -> arxiv.pdf
bash scripts/build_arxiv_pdf.sh --pdf-only # PDF only when arxiv.tex already current
```

# Neighborhood systems (Scott 1981, PRG-19, S1) -- foundations

Following Dana Scott, Lectures on a Mathematical Theory of Computation, Technical
Monograph PRG-19, Oxford (May 1981), Lecture I, Domains given by neighbourhoods.

Scott fixes a non-empty set `Delta` of tokens and considers a family `?` of subsets of `Delta`
(the neighbourhoods). The order is reversed relative to information: a smaller
neighbourhood carries more information. A finite sequence of neighbourhoods is
consistent when it has a common lower bound inside `?` (a `Z` in `?` contained in all of
them); a neighbourhood system is closed under intersections of consistent finite sequences.

This file formalizes the very first page of S1:

* Definition 1.1 -- `NeighborhoodSystem`: a family with `Delta` in `?` (condition (i)) and
closure under consistent binary intersections (condition (ii)).
* Factoid 1.1a / 1.1b -- Scott's recursive convention for the finite intersection
`?_{i < n} X_i` (`interUpTo`): the empty intersection is `Delta`, and the ^(n+1)-fold
intersection peels off the last factor.
* Theorem 1.1c -- "from (ii) we can extend the intersection property to any finite
sequence", and consequently a finite sequence is consistent iff its intersection
lies in `?`.

The S1 core is deliberately constructive: Scott uses partial filters so that the
basic theory avoids maximal-filter existence (Zorn/choice). Every theorem here depends only
on `propext`/`Quot.sound` (no `Classical.choice`).
-/

namespace Scott1980.Neighborhood

/-- Definition 1.1 (Scott 1981, PRG-19). A neighbourhood system over a token type
`a`. `mem X` means "X` is a neighbourhood" (X` in `?`), and `master` is Scott's least
informative neighbourhood `Delta` (the whole token set, "ask me no questions").

The two conditions are exactly Scott's:

* (i) `Delta` in `?` -- `master_mem`;
* (ii) whenever `X, Y, Z` in `?` and `Z` subseq X I Y, then `X I Y` in `?` -- `inter_mem`.

```

```

We keep `master` as a field (rather than hard-wiring `Set.univ`) to stay faithful to
Scott's `Delta` notation, and record Scott's standing assumption `? subseq ?(Delta)` as the
    field
`sub_master` (every neighbourhood is a subset of `Delta`). The latter is what makes the
    principal
filter `X` (Definition 1.7) contain `Delta`, and underlies the least element `False = Delta`.
    -/
structure NeighborhoodSystem (a : Type*) where
  /-- `mem X` holds iff `X` is a neighbourhood of the system (`X in ?`). -/
  mem : Set a -> Prop
  /-- Scott's distinguished least-informative neighbourhood `Delta`. -/
  master : Set a
  /-- (i) `Delta in ?`. -/
  master_mem : mem master
  /-- (ii) Closure under intersection of a *consistent* pair: if `X, Y, Z in ?` with the
  witness `Z subseq X I Y`, then `X I Y in ?`. -/

/-- Scott's *"very special circumstance"* (the prose after Examples 1.2-1.4): a family `?`
is **nested-or-disjoint** when any two of its members are either nested (one included in the
other) or disjoint. -/
def NestedOrDisjoint {a : Type*} (mem : Set a -> Prop) : Prop :=
  forall ?X Y : Set a?, mem X -> mem Y -> X subseq Y \/ Y subseq X \/ X I Y
    = {}

/-- **Factoid 1.4a (Scott 1981, PRG-19).** "In these systems two neighbourhoods are either
disjoint or one is included in the other": a family containing `Delta` whose members are
pairwise
nested-or-disjoint **is** a neighbourhood system. This uniformly explains why Examples 1.2,
1.3 and 1.4 satisfy Definition 1.1.

The verification of condition (ii) needs no choice: if `X, Y` are nested then `X I Y` is the
smaller (already in `?`); if they are disjoint then the consistency witness `Z subseq X I
Y = {}`
forces `Z = {}`, whence `X I Y = {} = Z in ?`. The caller supplies `sub_master` (Scott's
`? subseq ?(Delta)`) directly. -/

# Example 1.2 (Scott 1981, PRG-19, S1)

Scott's first worked example: tokens `Delta = {0, 1}` and neighbourhoods
`? = {{0, 1}, {0}, {1}}`.

We construct the neighbourhood system, prove it satisfies Definition 1.1, and classify
its domain elements (Definition 1.6): there are exactly three filters, and exactly one
partial element -- the bottom filter `{Delta}`.
-/

# Example 1.3 (Scott 1981, PRG-19, S1)

```

Scott's second worked example: tokens $\Delta = \{0, 1, 2\}$ and neighbourhoods $\tau = \{\{0, 1, 2\}, \{1, 2\}, \{2\}\}$.

We construct the neighbourhood system, prove it satisfies Definition 1.1, and classify its domain elements (Definition 1.6): there are exactly three filters in a linear chain $\text{False} < \{\Delta, \{1, 2\}\} < \{\Delta, \{1, 2\}, \{2\}\}$, with token 2 the sole total element.

This is a concrete finite computation (`fin_cases`/`simp`); footprint `[propext, Classical.choice, Quot.sound]` -- same as Example 1.2.

Example 1.4 (Scott 1981, PRG-19, S1)

Scott's third worked example: the **binary tree** of depth 2. Tokens are the finite binary sequences of length ≤ 2 , $\Delta = \{?, 0, 1, 00, 01, 10, 11\}$, and the neighbourhoods are the subtrees rooted at each node:

$\Delta = \{\Delta, \{0, 00, 01\}, \{1, 10, 11\}, \{00\}, \{01\}, \{10\}, \{11\}\}$.

We encode the seven tokens as Δ_7 :

token	Δ	0	1	00	01	10	11
----	---	---	---	---	---	---	---
Δ_7	0	1	2	3	4	5	6

so $\Delta_{\text{left}} = \{0, 00, 01\} = \{1, 3, 4\}$, $\Delta_{\text{right}} = \{1, 10, 11\} = \{2, 5, 6\}$, and the four leaves are the singletons $\{3\}, \{4\}, \{5\}, \{6\}$.

We build the neighbourhood system (Definition 1.1) and classify its domain elements (Definition 1.6): there are exactly **seven** filters. Unlike Example 1.3's linear chain, this is

the first example with **branching** -- at the partial elements $\Delta_{\text{elemZero}} / \Delta_{\text{elemOne}}$ one has a *choice* of how to refine toward one of the four total (leaf) elements.

This is a concrete finite computation ($\Delta_{\text{fin_cases}} / \Delta_{\text{simp}}$); footprint $\Delta_{[\text{proptext}, \text{Classical.choice}, \text{Quot.sound}]}$ -- same as Examples 1.2/1.3.

# Example 1.5 (Scott 1981, PRG-19, S1)

Scott's fourth worked example: tokens `Delta = {0, 1, 2, 3}` and `?` the family of all non-empty subsets of `Delta`.

> This system is a direct generalization of Example 1.2 ... The verification that the present
  `?`
> is a neighbourhood system rests on nothing more than the remark that sets are consistent in
  `?`
> iff they have a non-empty intersection.

We encode tokens as `Fin 4`, take `mem X := X.Nonempty`, and `master := Set.univ`. Condition (ii)
of Definition 1.1 is immediate: a consistency witness `Z subseq X I Y` that is itself non-empty makes
`X I Y` non-empty.

* Example 1.5 -- `neighborhoodSystem`.
* Factoid 1.5a -- `consistent_iff_inter_nonempty`: a finite prefix is consistent in `?` iff
  its
  intersection is non-empty (Scott's "remark").

Unlike Examples 1.2-1.4 this construction needs no `fin_cases`/`decide`: it is `Set.Nonempty`
bookkeeping, so it audits constructive (`[propext, Quot.sound]`).

# Example 1.B (Scott 1981, PRG-19, S1) -- binary sequences

Scott's recurring binary example, generalizing the finite binary tree of Example 1.4 to
*infinite* sequences. Take `Delta = Sigma*` with `Sigma = {0,1}` (the finite binary strings,
`?` = the empty
string), and for `sigma` in `Sigma*` let `sigmaSigma*` be the set of all *extensions* of `sigma`
`. The neighbourhoods are

`B = {sigmaSigma* ? sigma` in `Sigma*}`,

a neighbourhood being "all extensions of a fixed prefix `sigma`". We encode `Sigma* = List Bool
`, the

```

empty sequence $\tau = []$, concatenation $\text{sigmatau} = \text{sigma} ++ \text{tau}$, and the *initial-segment* relation $\text{sigma} \leq \text{tau}$ by mathlib's list-prefix order $\text{sigma} \leq \text{tau}$. The cone sigmaSigma is $\text{cone sigma} = \{\text{w} \mid \text{sigma} \leq \text{w}\}$.

Deliverables (all of the Example-1.B paragraph, lines 281-315 of the source):

```
* **Example 1.B / Exercise (`B` is a system).** `B` : NeighborhoodSystem Str, built from the
  prefix *trichotomy* via `ofNestedOrDisjoint` -- any two cones are nested or disjoint.
* **`sigmaFalse` (the finite elements).** `sigmaBot sigma = (cone sigma)`, the principal filter
  of `sigmaSigma`; its
  minimal neighbourhood is `sigmaDelta = cone sigma`.
* **Factoid `sigma_0False subseteq sigma_1False ? sigma_0` initial segment of `sigma_1`.** `
  sigmaBot_le_iff`.
* **Exercise (`sigma` in  $|B|$ ).** `sigmaElt sigma x`, and `sigmaElt sigma False = sigmaFalse`
  (`sigmaElt_bot`) justifying
  the `sigmaFalse` notation.
* **Factoid `x = ?_n sigma_nFalse`.** `mem_iff_exists_sigmaBot`: every `x` in  $|B|$  is the
  union of the finite
  elements `sigmaFalse` with `sigmaSigma` in  $x$  -- the concrete "limit of finite
  approximations" in  $|B|$ . (The
  countable *chain* form, with `sigma_n ? sigma_{n+1}` enumerated, needs choice and is left to
  the prose.)
```

```
Everything is **constructive** (`#print axioms subseteq {propext, Quot.sound}): list-prefix
  is decidable,
so the trichotomy is choice-free.

# Theorem 1.10 (Scott 1981, PRG-19, S1) -- the element-token system  $\{[X]\}$ 

Given any neighbourhood system  $\mathcal{?}$ , Scott replaces the tokens  $\Delta$  by the elements  $\{|?|\}$ 
themselves: for  $X$  in  $\mathcal{?}$  put

 $[X] = \{x \text{ in } |?| \mid x \text{ in } X\}$ ,

the set of elements that contain  $X$ . The family  $\{[X] \mid X \text{ in } \mathcal{?}\}$  is a neighbourhood system
over
 $\{|?|\}$ , and it determines a domain isomorphic to  $\{|?|\}$  (Definition 1.9). "The role of the
tokens
is simply to keep the inclusions (and intersections) of neighbourhoods sorted out."

We prove Scott's four facts:

* (1)  $\Delta = |?|$  -- bracket_master;
* (2)  $X, Y$  consistent in  $\mathcal{?}$  iff  $[X] \cap [Y] \neq \emptyset$  -- bracket_inter_nonempty_iff;
* (3)  $[X] \cap [Y] = [X \cap Y]$  (for  $X, Y$  in  $\mathcal{?}$ ) -- bracket_inter;
* (4)  $X$  in  $[X]$  -- principal_mem_bracket;

together with the one-one (bracket_injective), inclusion-preserving (bracket_subset_iff)
correspondence  $X \mapsto [X]$ , and finally the induced order-isomorphism  $\text{tokenIso} : |?| \cong \{[X] \mid X \text{ in } \mathcal{?}\}$ ,
giving  $\mathcal{?} \cong \text{tokenSystem}(\text{isomorphic\_tokenSystem})$ .

Everything is constructive (propxt, Quot.sound):  $[X]$ -membership is just  $x.\text{mem } X$ , and
the
filter laws mirror the constructive proofs for principal.

# Theorem 1.11 (Scott 1981, PRG-19, S1) -- closure of `|?|` under sequential `?` and ascending
`?`

If `?` is a neighbourhood system and `x_n` in `|?|` for `n = 0, 1, 2, ...`, then

* (i) `?_n x_n` in `|?|`;
* (ii) `?_n x_n` in `|?|`, **provided** `x_0` subseq x_1 subseq x_2 subseq ?` (an
    ascending chain).

We realize each as a concrete `Element`:

* `iInter x` has membership `X` in `?_n x_n` for all `n`, `X` in `x_n`. All four filter laws are
    pointwise. It is
    the **greatest lower bound** (`iInter_le`, `le_iInter`): Scott's "best element that
    approximates
    all of the `x_n`; exactly what is common to all".
* `iUnion x hmono` (with `hmono : Monotone x`) has `X` in `?_n x_n` if exists `n`, `X` in `x_n`.
    Only filter law (ii)
    (closure under `I`) needs the proviso: from `X` in `x_n`, `Y` in `x_m` take `k = max n m`,
    where
    monotonicity puts both `X, Y` in `x_k`, so `X I Y` in `x_k`. It is the **least upper bound
    **
    (`le_iUnion`, `iUnion_le`): "just what the increasing sequence approximates".

Everything is constructive (`[propext, Quot.sound]`).

# Exercise 1.12 (Scott 1981, PRG-19, S1) -- the final-segment system on `Nat`

Let `Delta = Nat` and take as neighbourhoods the final segments (tails)

`tail n = {m in Nat ? n <= m}`,

so `tail 0 = Nat = Delta` and `tail 0 supseteq tail 1 supseteq tail 2 supseteq ?` is a
descending chain (Scott's `{m ? m > n}`
is `tail (n+1)`). This generalizes Example 1.3 (a chain) to the countably infinite case.

Deliverables:

* `neighborhoodSystem : NeighborhoodSystem Nat` (the tails are pairwise nested, so Factoid 1.4a
applies) -- verifies it is a neighbourhood system.
* Finite elements. `fin n = (tail n)`, the principal filters; they form an ascending `?-
chain
`fin 0 ? fin 1 ? ?` (`fin_le_iff`, `fin_strictMono`).
* The limit / total element. `top = ?` itself (all tails) is the greatest element (`le_top
`),
is the unique total (maximal) element (`top_isTotal`, `isTotal_iff_top`).
* Classification (the "only one limit element" hint): every element is either a finite `fin
n`
or the limit `top` (`element_eq`). This single result is classical (it decides whether the
set
of indices in `x` is bounded -- `Nat.find` over a `not`-predicate); everything else is
constructive.

# Exercise 1.13 (Scott 1981, PRG-19, S1) -- the infinite binary system `B`, revisited

Scott: "Verify all the assertions made about the system `B` ... Draw a picture ... which
  includes nodes
for all `sigma` in `Sigma` ... and where the total elements lie. (The picture ... has to have
  limit nodes all
along the top.)"

The "assertions about `B`" are exactly the content of `ExampleB.lean`:

* `ExampleB.B` is a neighbourhood system (`ExampleB.nestedOrDisjoint`);
* `ExampleB.sigmaElt`/`sigmaElt_bot` realize Scott's `sigma_max` and `sigmaFalse` with `sigma_max` in
  `|B|`;
* `ExampleB.sigmaBot_le_iff` is "`sigma_0False` sqsub `sigma_1False` ? `sigma_0` initial segment
  of `sigma_1`";
* `ExampleB.mem_iff_exists_sigmaBot` is "`x = ?_n sigma_nFalse`".

This file supplies the limit nodes: for an infinite path `p : Nat -> Bool` we build the
element
`branch p` in `|B|` as the ascending union (Theorem 1.11(ii)) of the finite approximations
`sigma_nFalse = (p?n)False`, show every finite approximation approximates it (`
  branchSeq_le_branch`), and prove it
is a total (maximal) element (`branch_isTotal`). These are the nodes "along the top".

Constructive except `branch_isTotal`'s use of `B`'s structure (still `[proptext, Quot.sound]`).

# Exercise 1.14 (Scott 1981, PRG-19, S1) -- finite non-empty subsets of `Nat`

Let `Delta = Nat` and take as neighbourhoods the finite non-empty subsets of `Nat`,
together with `Delta`
itself. This is the infinite analogue of Example 1.5 (where `Delta` was finite).

Deliverables:

* `neighborhoodSystem : NeighborhoodSystem Nat` -- "Show that this is a neighbourhood system."
  Unlike
  the tail/binary examples this is not nested-or-disjoint (two finite sets may overlap
  partially),
  so condition (ii) is checked by hand: the consistency witness `Z subseq X I Y` keeps `X
  I Y` non-empty,
  and `X I Y` is finite as soon as either factor is.
* Finite elements. `fin h = X` (the principal filters), Scott's finite elements.
* Total elements. "What are the total elements?" The maximal filters are exactly the
  principals
  of singletons: `singleton_isTotal` shows `{n}` is total (a filter strictly above it would
  have
  to contain a set missing `n`, forcing `{}` in `?`).

Constructive (`[propext, Quot.sound]`).

# Exercise 1.15 (Scott 1981, PRG-19, S1) -- non-isomorphic "finite-only" domains

"Construct non-isomorphic infinite domains where all elements are finite but where there are no
infinite chains  $\langle x_n \rangle$  of elements with  $x_n \neq x_{n+1}$  for all  $n$ ."

We give two neighbourhood systems over  $\Delta = \text{Nat}$ :

* flat --  $\Delta = \{\text{Nat}\} \cup \{\{n\} \mid n \in \text{Nat}\}$  (the flat domain). Its elements are
  exactly False and the
  pairwise-incomparable atoms {n} (flat_classify), so all elements are finite/principal
  (flat_all_finite), every atom is maximal (flat_atom_maximal), there is no 3-chain
  (flat_no_three_chain) and hence no infinite ascending chain (flat_no_infinite_chain).
  It is
  infinite (flat_infinite).

* stem --  $\Delta = \{\text{Nat}, \{0,1\}\} \cup \{\{n\} \mid n \in \text{Nat}\}$  (a flat domain with one length-3 "
  stem"). It
  contains a strict 3-chain False < {0,1} < {0} (stem_three_chain). It too has only
  finite
  elements and no infinite ascending chain (same flat-with-stem classification; the formally
  decisive
  difference from flat is the 3-chain).

Since an order-isomorphism transports strict chains, the 3-chain in stem would force a 3-
chain in
flat, which has none: hence not (flat ≈ stem) (not_isomorphic). Two infinite, finite
-element,
chain-bounded domains that are not isomorphic.

The classification results are classical (they decide whether an element contains some atom);
the
constructions and the non-isomorphism argument are otherwise elementary.

# Exercise 1.16 (Scott 1981, PRG-19, S1) -- cofinite subsets of `Nat`

`Delta = Nat`, `? =` the *cofinite* subsets (`X?` finite). This is a neighbourhood system
(`cofiniteSystem`), closed under all finite intersections. Scott asks to show
`|?| ~ = (? (Nat), subseq)``.

The order-isomorphism `cofiniteIso : |?| ?o Set Nat` sends a filter `x` to its set of
**excluded points** `toExcluded x = {n ? {n}? in x}`, with inverse
`ofExcluded E = {Y cofinite ? Y? subseq E}` (a filter for *every* `E subseq Nat`). The
key reconstruction
lemma is `mem_compl_of_finite`: `?_{n in F} {n}? = F? in x` for finite `F` of points whose
single-point deletions are in `x`.

We also record `ofExcluded_univ_isTotal` / `le_ofExcluded_univ` -- the unique total element is
the
`sqsub` -top `ofExcluded Nat` (= all of `?`), matching the greatest element `Nat in ?(Nat)`
-- and
`fullSystem`, a second system (all subsets) closed under finite intersection.

`mem_compl_of_finite` uses `Set.Finite.induction_on` (and `Set.Finite` is classical), so the
classification lemmas are not choice-free; the *constructions* (`ofExcluded`, `cofiniteSystem`)
are `[propext, Quot.sound]`.

# Exercise 1.17 (Scott 1981, PRG-19, S1) -- rational open intervals on `ℚ`

`Delta = ℚ`; `ℚ` = the non-empty open intervals with rational endpoints, plus `Delta` itself
(`ratIntervalSystem`). The system law (`inter_mem`) reduces to the fact that the intersection
of
two rational intervals is empty or again a rational interval
(`Set.Ioo_inter_Ioo` with `max`/`min` of the rational endpoints): `inter_mem`.

For each real `t`, `filterAt t = {X in ℚ t in X}` is a filter (`filterAt`). These embed
`ℚ` into
`|?|` injectively (`filterAt_injective`, using rational density), so `|?|` contains a faithful
copy of the reals.

**Scope.** Scott's full classification of the total elements (the hint: for rational `t`,
intervals with `t` as a right-hand endpoint give a second total element at `t`) needs more
real analysis and is left to prose; we deliver the system, the point-filters, and their
injectivity. This is the first uncountable `Delta` of the block.

The constructions are `[propxt, Quot.sound]`; injectivity uses `exists_rat_btwn` (Archimedean,
classical).

# Exercise 1.18 (Scott 1981, PRG-19, S1) -- consistent subsets and filter intersections

Scott calls a subset `C` subseq ?` *consistent* iff every finite subset of `C` is consistent
in `?`.

This file formalizes (representing finite subsets as finite sequences drawn from `C`):

* `FinitelyConsistent C` -- every finite sequence from `C` is `Consistent`;
* a concrete `C = {A, B, Cc}` (over `Delta = {0,1,2}`, all-non-empty-subsets system) with three
  members, pairwise consistent (`family_pairwise_nonempty`) but **not** consistent
  (`not_finitelyConsistent`) -- `A I B I Cc = {}`;
* `sInf F hF` -- the intersection of a non-empty family `F` of filters is a filter, the
  greatest
  lower bound (`sInf_le`, `le_sInf`);
* `leastFilter C hCsub hC` -- the **least** filter containing a consistent `C`, with
  `subset_leastFilter` (`C subseq` it) and `leastFilter_le` (it is least). The intersection
  law uses
  the *append* of two finite sequences (`interUpTo_appendSeq`).

Constructive (`[propext, Quot.sound]`) except the counterexample's finite case-analysis.

# Exercise 1.19 (Scott 1981, PRG-19, S1) -- positive neighbourhood systems

Scott replaces condition (ii) of Definition 1.1 by the biconditional **(ii')**: whenever
`X, Y` in `?`, then `X ∩ Y != {}` ? `X ∩ Y` in `?`. The predicate `IsPositive` and the
builder
`ofPositive` (positive ? neighbourhood system) live in `Basic.lean`.

This file supplies the two examples requested by the exercise:

* `positiveExample` -- a genuinely positive system (all non-empty subsets of `Delta`, built
  with
  `ofPositive`), with `positiveExample_isPositive`;
* a non-positive neighbourhood system `notPositiveSystem` over `Delta = {0,1,2}` with
  `? = {Delta, {0,1}, {1,2}}`. It satisfies Definition 1.1 (the only overlapping pair `{0,1}`,
  `{1,2}` has intersection `{1}`, which has no consistency witness in `?`, so (ii) never
  fires) yet fails (ii'): `{0,1} ∩ {1,2} = {1}` is non-empty but is not a neighbourhood
  (`not_isPositive`). This is a small stand-in for Hoare's `Nat x Nat` example (Scott notes
  "smaller examples are of course possible").

Everything is `[propext, Quot.sound]`.

Exercise 1.20 (Scott 1981, PRG-19, S1) -- the power system $\mathcal{P}' = \{X\}$

For any neighbourhood system $\mathcal{P}$ over Δ , Scott takes $\Delta' = \mathcal{P}$ and $\mathcal{P}' = \{X \mid X \text{ in } \mathcal{P} \text{ and } Y \subseteq X\}$ (the *up-set* of X inside $\mathcal{P}$) -- *not* the principal filter of Definition 1.7, which is the *down-set* $\{Y \text{ in } \mathcal{P} \mid Y \subseteq X\}$. The exercise asks to show $\mathcal{P}'$ is *positive* and that $|\mathcal{P}'| \cong |\mathcal{P}|$, with finite elements and tokens of $\mathcal{P}'$ in one-one correspondence.

This file (named `upSet` to avoid the `principal`/`X` collision):

```
* `upSet`, `upSet_inter` ( $X \cap Y = (X \cap Y)$ ), `upSet_subset_iff` ( $X \subseteq Y \leftrightarrow X \subseteq Y$ ),
  `upSet_injective`;
* `powerSystem` : NeighborhoodSystem (Set a) and `powerSystem_isPositive`;
* the mutually-inverse toPower/ofPower and the order-iso powerIso :  $|\mathcal{P}| \cong |\mathcal{P}'|$ , hence
  `isomorphic_powerSystem` :  $V \cong V.$ powerSystem;
* `toPower_principal` : the iso carries the finite element  $X$  to the finite element of  $\mathcal{P}'$ 
  generated by the token  $X$ , i.e. tokens of  $\mathcal{P}' \leftrightarrow$  finite elements one-one.
```

Note the variance: $X \mapsto X$ is inclusion-*preserving* (`upSet_subset_iff`), unlike Def 1.7's

`principal`. Everything is `[propext, Quot.sound]`.

# Exercise 1.21 (Scott 1981, PRG-19, S1) -- Theorem 1.10 in greater detail

Scott asks to work out the proof of Theorem 1.10 more fully and to observe two further
properties of the element-token system  $\{[X]\}$  over  $|?|$ :

* it is positive (`tokenSystem_isPositive`), giving "in a different way the same kind of
  conclusion as in 1.20";
* it is complete (`tokenSystem_complete`): every filter is fixed by a unique point -- the
  point whose filter of containing neighbourhoods it is. We formalize "fixed by a point" as
  `IsComplete`, and derive it from the bijection `tokenIso` of Theorem 1.10
  (`tokenSystem_toToken_bijective`). Thus tokens and (partial) elements are identified.

Finally, consistency of  $\{X_i \mid i < n\}$  is equivalent to
 $\{?_{i < n} [X_i] \neq \{\}\}$  (`consistent_iff_iInter_bracket_nonempty`), the finite generalization
of
Theorem 1.10(2) via Theorem 1.1c.

Everything is `[proptext, Quot.sound]` (the corollaries inherit the constructive proofs of
Theorem 1.10 / Theorem 1.1c).

# Exercise 1.22 (Scott 1981, PRG-19, S1) -- the topology on `|?|`

> **EXERCISE 1.22.** (For topologists). Show that the neighbourhoods `[X]` for `X` in `?` make
> `|?|` into a topological space where the open subsets `?` subseteq `|?|` can be characterized
> by the
> following two conditions:
>
> (i) whenever `x` in `?` and `x sqsub y` in `|?|`, then `y` in `?`; and
> (ii) whenever `x` in `?`, then `[X]` subseteq `?` for some `X` in `x`.
>
> Prove also that the inclusion relation on `|?|` can be defined topologically as:
>
> (iii) `x sqsub y` iff for all open `?` subseteq `|?|`, if `x` in `?` then `y` in `?`.

Here `[X] = {x in |?| ? X in x}` (Scott's notation from Theorem 1.10): the set of elements
(filters) of which `X` is a member. We call it `basicOpen X`.

## What is proved

* `basicOpen` -- Scott's `[X]`, with `mem_basicOpen` the membership unfolding.
* `instTopologicalSpaceElement` -- the topology on `V.Element`: `?` is open iff every point of
  `?` has a basic neighbourhood `[X]` (`X` in `x`) contained in `?`. This is condition (ii);
  the
  three topology axioms are verified directly (the basic opens are closed under finite `I`,
  with
  `[Delta] = |?|` the whole space, so they form a base).
* `isOpen_basicOpen` -- each `[X]` is open.

```

```

* `isOpen_iff_upper_basic` -- the characterization: `IsOpen ? <-> (i) /\ (ii)`. Note (ii)
  already
  pins down openness; (i) (upward closure under `sqsub`) is a consequence of (ii), recorded
  separately as `isOpen_isUpperSet`. We keep both to match Scott's statement.
* `le_iff_isOpen_imp` -- condition (iii): `x sqsub y <-> forall ? open, x in ? -> y
  in ?`. This says `sqsub` is
  the (opposite of the) specialization preorder; `specializes_iff_le` makes the bridge to
  Mathlib's `?` explicit.

```

The space is T_0 but not in general T_1 /Hausdorff (the specialization order sqsub is a genuine partial order, recoverable from the topology by (iii)); the open-ended limit-point questions of the exercise need Definition 1.7 (X) and are deferred.

# Exercise 1.23 (Scott 1981, PRG-19, S1) -- the greedy total element of a countable system

Scott: suppose  $\mathcal{X} = \{X_0, X_1, \dots\}$  is countable and the consistency of finite sequences of
neighbourhoods is *decidable*. Then the greedy sequence

...
 $Y_0 = X_0$ 
 $Y_{n+1} = X_{n+1}$  if  $X_{n+1}$  is consistent with  $Y_0, \dots, Y_n$ ;
        $= Y_n$  otherwise.
...

is well defined, and  $\{Y_0, Y_1, \dots\}$  is a **total** element of  $\mathcal{X}$ . (Hint: first show that
 $Y_0, \dots, Y_{n-1}$  is consistent for every  $n$ .)

This file formalizes the greedy construction over an enumeration  $\text{enum} : \text{Nat} \rightarrow \text{Set } \alpha$  of
 $\alpha$ ,
encoding "consistency of the prefix + candidate is decidable" as  $[\text{DecidablePred } V.\text{mem}]$  (by
Theorem 1.1c, a prefix is consistent iff its running intersection is a neighbourhood). We carry
the *state*  $(Y_n, \{i \leq n \mid Y_i\})$ ; the running intersection  $\text{acc } n$  is exactly  $\text{interUpTo } Y (n+1)$ 
and is always a neighbourhood, which is the hint  $Y.\text{prefix\_consistent}$ .

*  $\text{greedyElement}$  -- the filter  $\{X \mid \exists i < n, Y_i \subseteq X \text{ for some } n\}$  generated by
 $\langle Y_n \rangle$ ;
*  $\text{greedyElement\_isTotal}$  -- under surjectivity of  $\text{enum}$ ,  $\text{greedyElement}$  is maximal: any  $W$ 
in a larger filter  $\mathcal{Z}$  is some  $\text{enum } k$ ; if greedy *skipped* it then  $W$  was inconsistent
with
the prefix, contradicting  $\mathcal{Z}$ 's closure under intersection.

The construction is  $[\text{propext}, \text{Quot.sound}]$  given the supplied  $\text{DecidablePred}$ . -/

# Exercise 1.24 (Scott 1981, PRG-19, S1) -- every partial element extends to a total one (AC)

Scott (for set theorists): using the Axiom of Choice, prove that in every domain a partial
element
can always be extended to a total element. (Hint: the union of every transfinite chain of
filters
is again a filter.)

This file formalizes:

* `chainUnion C hne hchain` -- the union `? C` of a non-empty **chain** `C` of filters is
itself a

```

```

filter (V.Element); the only non-trivial axiom is `inter_mem`, which uses chain-
directedness to
find a single member of `C` containing both factors. Plus `le_chainUnion` (every member of
the
chain is `sqsub` the union).
* `exists_total_ge x` -- **with Zorn's lemma** (`zorn_le_nonempty_Ici_0`), every element `x`
has a
*total* element `t` above it (`x sqsub t /\ IsTotal t`). The chains in `Ici x` are
bounded above by
their `chainUnion`, so Zorn produces a maximal -- i.e. total -- element.

Whether this is *equivalent* to AC is left as prose (Scott's question); we do not formalize the
reversal. This is the explicitly **classical** exercise: `exists_total_ge` legitimately uses
`Classical.choice` through `zorn_le_nonempty_Ici_0`. The `chainUnion` *construction* is choice-
free
(`[proptext, Quot.sound]`). -/

# Exercise 1.25 (Scott 1981, PRG-19, S1) -- final segments of an ordinal

Scott: let `Delta` be a well-ordered set (ordinal) and let `?` be the family of non-empty *
      final*
segments of `Delta`. Describe `|?|`; are all elements finite; is every approximation to a
      finite
element finite?

For a linear order, the *final segments* are exactly the non-empty **upper sets** (`IsUpperSet
`).
Any two upper sets of a linear order are nested (`upperSet_subset_or`), so the family is a
neighbourhood system by Scott's nested-or-disjoint criterion (`finalSegmentSystem`).

**Classification of `|?|`.** For a *well-order* every non-empty upper set is `Set.Ici a` with `
a`
its minimum (`exists_Ici_of_mem`). Hence a filter `x` is completely described by its trace
`lowerSetOf x = {a ? Ici a in x}`, which is a **non-empty lower set** of `Delta`, and `x |->
      lowerSetOf x`
is an order isomorphism

`|?|` ?o {S : Set Delta ? S non-empty lower set} (ordered by `subseq`) -- `
      finalSegmentClassify`.

So `|?|` is the lattice of non-empty initial segments of `Delta` (the "cuts" of `Delta`).

**Total / finite.** The greatest element is the filter of *all* neighbourhoods (`topElement`),
which is the unique total element (`topElement_isTotal`, `eq_topElement_of_isTotal`). The
      finite
elements are the principal filters `(Ici a)`. When `Delta` has no greatest element (e.g. `Nat =
      ?`) the
total element is **not** finite (`topElement_not_principal_of_noMax`): not all elements are
      finite.

The system and `Ici` lemmas are `[propext, Quot.sound]`; the classification's surjectivity uses
the well-ordering (`WellFounded.has_min`), so it is classical. -/

# Exercise 1.26 (Scott 1981, PRG-19, S1) -- ideals of a commutative ring

Scott (for algebraists): let `A` be a commutative ring with unit and let `Delta` be the set of
  finite
subsets `F ⊆ A`. Put

`I(F) = {G ∈ Delta ∣ F ⊆ G}` (the ideal generated by `G`).

Then the sets `I(F)` form a neighbourhood system and the corresponding domain is isomorphic to
  the
poset `(Ideals A, ⊆)`.

This file formalizes (`Delta = Finset A`, tokens are finite subsets):

* `IFamily F = {G ⊆ A ∣ F ⊆ G}` and `ringSystem`, the neighbourhood system. The
  master is
  `I({}) = Delta`, and `I(F_1) ∩ I(F_2) = I(F_1 ∪ F_2)` so the family is closed under all
  intersections
  (no consistency hypothesis needed -- `inter_mem` is unconditional).
* `idealOf x = {a ∈ I({a}) ∣ a ∈ x}` -- a filter's elements collapse to a genuine ideal;
  conversely
  `ofIdeal J = {I(F) ∣ F ⊆ A, F ⊆ J}`.
* `ringIso : Ideal A → Ideal A` -- the order isomorphism to `(Ideals A, ⊆)` (Scott's
  claim). The token
  order is reverse (bigger `F` ⊆ smaller `I(F)`), but the resulting filter order matches
  ideal
  inclusion.

Constructive (`[propext, Quot.sound]`): the round trips are equational, the only inputs being
mathlib's `Ideal.span` API. -/

# Exercise 1.27 (Scott 1981, PRG-19, S1) -- bounded sets and least upper bounds

Scott introduces *bounded* sets of elements as the analogue, for  $|?|$ , of *consistent*
sequences of neighbourhoods. A set  $X$  subseq  $|?|$  is *bounded* iff it has an upper bound
 $y$  in  $|?|$  ( $x$  sqs  $y$  for all  $x$  in  $X$ ), and then

 $\text{sqsup } X = \{y \mid x \text{ sqs } y \text{ for all } x \text{ in } X\}$ 

is its *least upper bound*. This file formalizes:

* Bounded  $X$  and  $\text{sSup } X$   $hX := \text{sInf (upper bounds of } X)$  -- the upper-bound family is non-
empty
exactly because  $X$  is bounded, so we reuse  $\text{sInf}$  from Exercise 1.18; the lub laws
 $\text{le\_sSup}$  /  $\text{sSup\_le}$  are then immediate from  $\text{le\_sInf}$  /  $\text{sInf\_le}$ ;
* consistent\_pair\_iff\_bounded -- for  $U, W$  in  $?$ , the pair  $\langle U, W \rangle$  is Consistent iff
 $\{U, W\}$  is bounded ("boundedness is for elements what consistency is for neighbourhoods");
* bounded\_iff\_finite\_bounded -- with the aid of Exercise 1.18,  $X$  is bounded iff every
finite subset of  $X$  is bounded; the hard direction builds the bound as the leastFilter
of  $C = \{x \text{ in } X \mid x\}$ , whose finite consistency comes from the finite bounds.

The constructions ( $\text{sSup}$ ) are  $\text{[propxt, Quot.sound]}$ . The hard direction of
bounded\_iff\_finite\_bounded selects a finite witness set via Classical.choice; this is a
*proof*, so the construction stays choice-free.

# Lecture II (S2) -- approximable mappings: Definitions 2.1, 2.2 and Theorems 2.5-2.7

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981),
Lecture II,
*Approximable mappings*. A mapping of domains that "preserves the spirit of approximation" is
given
not by a function on ideal elements but by a **relation between neighbourhoods**: `X f Y` reads
"if
the input is approximated at least as well as by `X`, then the output is approximated at least
as
well as by `Y`."

This file formalizes the S2 core:

* **Definition 2.1** -- `ApproximableMap V_0 V_1`: a relation `f` subseq ?_0 x ?_1` with
(i) `Delta_0 f Delta_1` (`master_rel`),
(ii) `X f Y -> X f Y' -> X f (Y I Y')` (`inter_right`, the consistency/intersectivity
condition),
(iii) `X f Y -> X' subseq X -> Y subseq Y' -> X' f Y'` (`mono`, monotonicity:
sharper input, blunter output).
We carry `rel_dom`/`rel_cod` recording `f` subseq ?_0 x ?_1`.
* **Proposition 2.2** -- every approximable mapping determines an elementwise function
`toElementMap f : |?_0| -> |?_1|`, `f(x) = {Y ? exists X in x, X f Y}`, which is a
filter (i)-(iii) are
*all* used); the relation is recovered by `rel_iff_mem_principal` (`X f Y <=> Y in f(X)`);
the map
is monotone (`toElementMap_mono`); and two approximable maps are equal iff they induce the
same
elementwise map (`ext_of_toElementMap`).
* **Theorem 2.5** -- neighbourhood systems and approximable maps form a **category**: identity
`idMap` (`X I_D Y <=> X subseq Y`), composition `comp g f` (`X (g comp f) Z <=>
exists Y, X f Y /\ Y g Z`), with the
identity laws `idMap_comp`/`comp_idMap` and associativity `comp_assoc`.
* **Proposition 2.6** -- the elementwise action is a **functor** to sets and functions:
`toElementMap_idMap` (`I_D(x) = x`) and `toElementMap_comp` (`(g comp f)(x) = g(f(x))`).
* **Theorem 2.7** -- every domain **isomorphism** `e : |?_0| ?o |?_1|` (Definition 1.9) comes
from an
approximable map: `ofIso e` with `toElementMap_ofIso` (`(ofIso e)(x) = e(x)`), packaged as
`exists_approximable_of_iso`; moreover `e` carries finite (principal) elements to finite
elements
(`exists_principal_eq_apply_principal`), via the directed-union construction `sSupDirected`.

Everything in this file is **choice-free** (`#print axioms subseq {proptext, Quot.sound}`);
the only
classical lemma is `ext_of_toElementMap`, which decides neighbourhood membership by `by_cases`
(`Classical.em`). -/

/-- **Theorem 2.7 (Scott 1981, PRG-19) -- finite elements go to finite elements.** A domain
isomorphism `e` carries the finite (principal) element `X` to a finite element `Y` of the other
domain. Following Scott: with `w = e(X)`, the set `S = {e^-1(Y) ? Y in w}` is directed (
intersections
of members of `w` give upper bounds), so its union `z = ? S` is an element (`sSupDirected`).
One shows
`z = X` (each `e^-1(Y) sqsub e^-1(w) = X`, and conversely `w sqsub e(z)` forces `X = e^-1(w)
) sqsub z`); then
`X in z` lands in some `e^-1(Y)`, giving `w sqsub Y`, while `Y sqsub w` is automatic --
so `w = Y`. -/
theorem exists_principal_eq_apply_principal (e : V_0.Element ?o V_1.Element)

# Lecture II (S2) -- Exercises 2.8-2.12 and 2.19 (the algebra of approximable mappings)

Following Dana Scott, PRG-19 (1981), Lecture II. This file collects the structural exercises
about
approximable mappings, all built on `Approximable.lean`:

* Exercise 2.8 -- an approximable map is determined by its action on finite (principal)
elements

```

```

(`eq_of_toElementMap_principal`); and any monotone function on finite elements extends to
an
approximable map (`ofMono`, `toElementMap_ofMono_principal`).
* Exercise 2.9 -- Scott's formula  $f(x) = \bigvee \{f(X) \mid X \text{ in } x\}$  (`
toElementMap_mem_iff_principal`).
* Exercise 2.10 -- the pointwise meet of two maps:  $h(x) = f(x) \sqcap g(x)$  (`interMap`).
* Exercise 2.11 --  $\sqcup$  is closed under directed unions (`iSupDirected`, with
`mem_iSupDirected`/`le_iSupDirected`/`iSupDirected_le`), and approximable maps preserve
them
(`toElementMap_iSupDirected`).
* Exercise 2.12 -- a directed family of approximable maps has a pointwise union that is
again
approximable (`iSupMap`, `mem_toElementMap_iSupMap`).
* Exercise 2.19 -- two-variable approximable maps  $f : ?_0 \times ?_1 \rightarrow ?_2$  as ternary
relations
(`ApproximableMap_2`), with the Proposition 2.2 analogue (`toElementMap_2`,
`rel_2_iff_mem_principal`).

```

All constructions are **choice-free** (`#print axioms subseq {propeq, Quot.sound}`); the
two
`eq\_of\_...`/uniqueness lemmas decide membership by `by\_cases` and are therefore classical,
exactly like
`ext\_of\_toElementMap`. -/

# Example 2.3 (Scott 1981, PRG-19, S2) -- the parity map `f : B -> T`

Scott's first approximable mapping. Reading a binary sequence left to right, count the number `n`
of `0`'s seen *before the first* `1`; the output is `true` if `n` is even, `false` if `n` is
odd,
and `False` while the input is still an unbroken string of `0`'s (which has consistent
extensions of
both parities). Concretely

`f(0?1False) = true` if `n` even, `false` if `n` odd; `f(0^inf) = False`.

Here `B` is the binary system (`ExampleB`) and `T` is the two-token domain of Example 1.2,
whose two
total elements we use as `true`/`false` and whose unique partial element is `False`.

We model the relation by a parity scanner `scan : Sigma* -> Option Bool`:
`scan` returns `none` while no `1` has appeared and `some b` (with `b` the parity-of-leading-
zeros)
once the first `1` is found. The neighbourhood relation is

`X f Y <-> exists sigma, X = sigmaSigma* /\ Y in valElt (scan sigma)`,

where `valElt none = False`, `valElt (some true) = true`, `valElt (some false) = false`. The
cone `sigmaSigma*`
has a unique generating prefix (`cone_injective`), so this is well defined, and `scan` is *
stable*
under extension (`scan_append`), which is exactly the monotonicity (Def 2.1(iii)).

Definition 2.1(i)-(iii) all check out, giving `parityMap : ApproximableMap B T`. (The `B`-side
reasoning is choice-free; `parityMap` nonetheless pulls `Classical.choice` through the concrete

```

```

codomain `T` of Example 1.2, whose `simp`/`fin_cases` proofs already do -- pre-existing and
  harmless.)

# Example 2.4 (Scott 1981, PRG-19, S2) -- eliminating the first run of `1`'s, `g : B -> B`

Scott's second approximable mapping reads a binary sequence left to right and "eliminates the
first
consecutive run of `1`'s while copying all the other digits." Thus

`g(0? 1? 0 x) = 0?^+1 x` (for `k > 0`), `g(1^ inf) = False`, `g(0? 1^ inf) = 0?`.

It is instructive because it turns *total* inputs (e.g.  $1^\infty$ ) into *partial* outputs.

We give the *guaranteed finite output*  $\text{out} : \text{Sigma}^* \rightarrow \text{Sigma}^*$  for each finite input
prefix via a two-state
scan:  $\text{out}$  copies leading  $0$ 's and, on the first  $1$ , hands over to  $\text{del}$ , which swallows the
run
of  $1$ 's and -- on the terminating  $0$  -- emits that single  $0$  and copies the rest verbatim.
The
elementwise value on the finite element  $(\text{sigmaSigma})^*$  is  $((\text{out sigma})\text{Sigma})^*$ , so the
neighbourhood relation is

 $X \text{ g } Y \iff \text{exists sigma, } X = \text{sigmaSigma}^* \wedge (\text{out sigma})\text{Sigma}^* \text{ subseq } Y \wedge Y \text{ in } B^*.$ 

 $\text{out}$  is prefix-monotone ( $\text{out\_mono} : \text{sigma} \leq \text{sigma}' \rightarrow \text{out sigma} \leq \text{out sigma}'$ ), which
gives Definition
2.1(iii); (i) and (ii) are the principal-filter facts for the cone  $(\text{out sigma})\text{Sigma}^*$ .
Constructive.

**Exercise 2.17, second half.** Scott also asks to show that  $\text{runMap}$  is *uniquely* determined
among approximable mappings by the four equations  $\text{g}(0x) = 0\text{g}(x)$ ,  $\text{g}(11x) = \text{g}(1x)$ ,
 $\text{g}(10x) = 0x$ ,  $\text{g}(1) = \text{False}$  ( $\text{SatisfiesRunEquations}$ ). We check  $\text{runMap}$  itself satisfies
them
( $\text{runMap\_satisfies}$ , using the two "shift formulas"  $\text{runMap\_toElementMap\_sigmaElt}$  /
 $\text{sigmaElt\_runMap\_toElementMap}$ , so the statement is non-vacuous) and then prove uniqueness
( $\text{eq\_runMap\_of\_satisfies}$ ): the recursive core ( $\text{key}$ ) pins down any such  $\text{g}$  on every
principal
element  $\text{sigmaFalse}$ , peeling *one* token of  $\text{sigma}$  at a time, mirroring  $\text{out}$ 's own case
split; the base case
 $\text{sigma} = []$  is the only place order theory ( $\text{B.bot\_le}$ ) enters, everything else being pure
substitution into the equations. Constructive except for the  $\text{by\_cases}$  in  $\text{ApproximableMap.ext}$ 
`
( $\text{\#print axioms subseq \{proptext, Classical.choice, Quot.sound\}}$ ). -/

# Exercise 2.13 (Scott 1981, PRG-19, S2) -- approximable maps are the continuous functions

> EXERCISE 2.13. (For topologists.) Recall Exercise 1.22 where it was shown that any domain
>  $|?|$  is a topological space. Prove from Exercise 2.9 that the functions  $f : |?_0| \rightarrow |?_1|$ 
> determined by approximable mappings are exactly the continuous functions between these
> spaces.*

This file closes the loop between the S2 theory of approximable mappings (Approximable.lean,
ApproximableExercises.lean) and the Exercise 1.22 topology on  $|?|$  (Exercise122.lean):

* continuous_toElementMap -- every approximable mapping  $f$  induces a continuous
function
 $x \mapsto f(x)$ . Scott's hint: by Exercise 2.9,  $f^{-1}[Y] = \{x \mid f(x) \in Y\}$ , so the
inverse image
of a basic open is a union of basic opens, hence open.
* continuous_monotone -- a continuous  $c : |?_0| \rightarrow |?_1|$  is monotone for sqsub (
the order is the
specialization order, le_iff_isOpen_imp).
* mem_iff_principal_of_continuous -- Scott's union formula for a continuous  $c$ :
 $Y \in c(x) \iff \exists X \in x, Y \in c(X)$ . (Forward:  $c^{-1}[X]$  open  $\Rightarrow x$ ; reverse:
 $x \sqsub x + \text{monotone}$ .)
* ofContinuous -- the approximable mapping of a continuous function, built from ofMono
on the
finite elements  $X \mapsto c(X)$  (monotone by continuous_monotone).
* toElementMap_ofContinuous -- the round trip: ofContinuous c hc induces exactly  $c$ 
((ofContinuous c hc)(x) = c(x)), combining Exercise 2.9 with the union formula.

Together:  $f \mapsto \text{toElementMap } f$  and  $c \mapsto \text{ofContinuous } c$  exhibit approximable mappings
 $|?_0| \rightarrow |?_1|$ 
and continuous functions  $|?_0| \rightarrow |?_1|$  as the same thing.

Choice-free apart from the ofMono/Exercise-2.9 ingredients (whose uniqueness companions are
the
only classical pieces). -/

/-- **The converse of `continuous_toElementMap`/`continuous_monotone`, in domain-theoretic form
.**
A monotone function that also preserves directed unions is topologically continuous -- the
standard
"Scott continuity ? order-theoretic continuity" bridge, proved directly from algebraicity
rather
than through a general topological-basis argument: given `x` in  $c^{-1}U$ , decompose `x` as the
directed
union of its principal approximants (`eq_iSupDirected_principal`); `c` preserving the union
puts
`c x` there too, so openness of `U` finds a witness `Y` in *some* `c(X)` (`X` in `x`);
monotonicity of
`c` then transfers `Y` in `c(X)` up to every `x` in  $[X]$ , giving  $[X]$  subsequence  $c^{-1}U$ . -/

# Exercise 2.14 (Scott 1981, PRG-19, S2) -- the neighbourhood correspondence `phi` of an
isomorphism

> **EXERCISE 2.14.** Let `f : |?_0| -> |?_1|` be an isomorphism between domains. Let `phi : ?
  _0 -> ?_1` be
> the one-one correspondence between neighbourhoods provided by Theorem 2.7 where `f(X) = phi(X
  )`
> for all `X` in `?_0`. Show that the approximable mapping determined by `f` is just the
  relationship
> `phi(X) subseteq Y`. In addition prove that if `X, X'` in `?_0` are consistent, then
> `phi(X I X') = phi(X) I phi(X')`.
> Remark that the isomorphisms between domains correspond exactly to the isomorphisms between
> neighbourhood systems (in the sense of one-one inclusion preserving correspondences).

```

```

Theorem 2.7 (exists_principal_eq_apply_principal) says a domain isomorphism e : |?_0| ?o |?_1|
carries each finite element X to a finite element Y. We extract the witness Y by
Classical.choose, getting phi with phi_spec : e(X) = phi(X):

* phi e hX, phi_mem, phi_spec -- the neighbourhood correspondence phi of e.
* rel_ofIso_iff -- the approximable mapping of e is exactly phi(X) subseq Y:
  (ofIso e).rel X Y <=> ?_1 Y /\ phi(X) subseq Y (for X in ?_0).
* phi_inter -- **phi(X I X') = phi(X) I phi(X') for *consistent* X, X' (i.e. X I X'
  in ?_0).
  The proof goes through the order structure: (X I X') is the **least upper bound** (join)
  of
  X, X' in |?_0| (note the inclusion order is *reversed*); e and e.symm are monotone,
  so
  they preserve this join, and the join of two consistent principals A, B in |?_1| is
  (A I B).

phi is Classical.choose-based, hence noncomputable and classical; the order-theoretic
proofs of
rel_ofIso_iff/phi_inter are otherwise choice-free (propext, Quot.sound). -/

Exercise 2.15 (Scott 1981, PRG-19, S2) -- the one-token system $\mathcal{T}$ (Sierpinski space)

```
> **EXERCISE 2.15.** (For topologists.) Consider the one-token system with  $\mathcal{T} = \{\{0\}, \{\}\}$ . We
  can
> regard  $\mathcal{T}$  as having just two finite elements  $\text{False}$  and  $\text{top}$ , where  $\text{False} \sqsubseteq \text{top}$ . For any system  $\mathcal{U}$ ,
> show that the open subsets  $U$  of  $\mathcal{T}$  are in a one-one correspondence with the approximable
> mappings  $f : \mathcal{U} \rightarrow \mathcal{T}$ , where the correspondence is given by  $U = \{x \mid f(x) = \text{top}\}$ . What
  are the
> open subsets of  $\mathcal{T} \times \mathcal{T}$  of  $\mathcal{T} \times \mathcal{T}$  of  $\mathcal{T} \times \mathcal{T}$ ?
```

We take the token type to be $\text{Fin } 1$, so the master neighbourhood $\Delta = \{0\}$ is Set.univ and the

two neighbourhoods of $\mathcal{T}$ are $\Delta = \text{univ}$ and $\{\}$. Then $\mathcal{T}$ has exactly two elements: $\text{False} = \Delta = \{0\}$ and $\text{top} = \{\}$, with $\text{False} \sqsubseteq \text{top}$ (botElt_le_topElt , strict by botElt_ne_topElt).

The space $\mathcal{T}$ is **Sierpinski space**: its open sets are $\{\}$, $\{\text{top}\}$ ($\text{basicOpen } \{\}$), and the whole space; $\{\text{False}\}$ is **not** open (False is the generic point, $\text{not_isOpen_singleton_botElt}$).

The main theorem (openSet_equiv_map) is the Sierpinski-space adjunction "open sets = continuous

maps to $\mathcal{T}$ ", here in the approximable-mapping guise:

```
* `openToMap U hU : ApproximableMap ? ?` -- the map with  $f(x) = \text{top} \iff x \in U$ , built
  **choice-free**
  as the neighbourhood relation  $X \sqsubseteq Y \iff X \in \mathcal{U} \wedge Y \in \mathcal{U} \wedge (Y = \{\} \rightarrow X \in U)$ 
  (monotone because  $U$ 
  is open, i.e. an upper set);
* `mapToOpen f := {x \mid f(x) = top}` -- open ( $\text{isOpen\_mapToOpen}$ ), being the preimage of the
  open point
   $\{\text{top}\} = \{\{\}\}$  under the continuous  $x \mapsto f(x)$  (Exercise 2.13);
* `openSet_equiv_map : {U // IsOpen U} \to ApproximableMap ? ?` -- the two are mutually inverse.
```

For the opens of $\mathcal{T}$ and $\mathcal{T} \times \mathcal{T}$: $\mathcal{T}$ (two incomparable totals true , false above False) has opens

generated by the two open points $\{\text{true}\} = \{\text{true-total}\}$ and $\{\text{false}\} = \{\text{false-total}\}$; $\mathcal{T} \times \mathcal{T}$'s

opens are generated by the basic cones $[\sigma, \Sigma]$. We record only $\mathcal{T} \times \mathcal{T}$'s opens in Lean.

Choice-free ($\text{\#print axioms subteq \{propext, Quot.sound\}}$) apart from the $\text{eq_of_toElementMap_principal}$

uniqueness step inherited from Exercise 2.8. -/

# Exercise 2.16 (Scott 1981, PRG-19, S2) -- the prefixing map `x |-> sigmaX` is approximable

In Lecture I (Example 1.B) Scott defined, for each finite string `sigma` in `Sigma*`, the
elementwise operation
`x |-> sigmaX` on `|B|` (`ExampleB.sigmaElt`). Exercise 2.16 asks whether this mapping is *
approximable*.
It is: the witnessing neighbourhood relation is

`X f Y <-> X, Y in B /\ sigmaX subseq Y`,

i.e. "the prefixed input cone `sigmaX` is at least as sharp as `Y`." We package it as
`sigmaMap sigma : ApproximableMap B B` and show its elementwise action is exactly `sigmaElt
sigma`
(`toElementMap_sigmaMap`).

**Second half.** Scott also asks to show that the parity map `f : B -> T` of Example 2.3
(`Example23.parityMap`) is *uniquely* determined among approximable mappings by the three
equations `f(1x)=true`, `f(01x)=false`, `f(00x)=f(x)` (`SatisfiesParityEquations`). We check

```

```

`parityMap` itself satisfies them (`Example23.parityMap_toElementMap_sigmaElt`, so the
statement
is non-vacuous) and then prove uniqueness (`eq_parityMap_of_satisfies`): the recursive core
(`key`) pins down any such `g` on every principal element `sigmaFalse`, peeling two tokens of `
sigma` at a
time (mirroring `scan`'s own recursion); the base case `sigma = []` and the leftover singleton
`s sigma = [false]` are the two places genuine order theory (flatness of `T`, `Example23.
eq_botElt_of_le`)
enters, everything else being pure substitution into the equations.

```

```

Constructive except for the `by_cases` in `ApproximableMap.ext`'s use of `Classical.em`
(`#print axioms subseq {propext, Classical.choice, Quot.sound}`). -/

/-- **The recursive core of uniqueness.** Any `g` satisfying the three equations agrees with
`parityMap` on every principal (finite) element `sigmaFalse`. Recursion peels *two* tokens at a
time
(mirroring `scan`'s own recursion `scan(00tau)=scantau`): `1tau` and `01tau` are pinned
directly by
`hg.one`/`hg.zeroOne` for *any* tail (no recursion needed there); `00tau` reduces to `tau` by
`hg.zeroZero`, decreasing structurally. The base case `sigma = []` and the leftover singleton
`siga = [false]` (an odd trailing zero, never reached by the two-at-a-time step) are the two
places
genuine order theory enters: `False <= 1False` and `False <= 01False` force `g(False) <=
true` and `g(False) <= false`, and
`False` is the *only* element below both (`eq_botElt_of_le`, `T`'s flatness); the singleton
then
follows by squeezing `g(0False)` between `False` and `g(00False) = g(False)` via monotonicity.

# Exercise 2.18 (Scott 1981, PRG-19, S2) -- the "spacing" map `h : ? -> ?`

```

```

> **EXERCISE 2.18.** What is the meaning in words of the approximable mapping `h : ? -> ?`,
  where
> `h(0x) = 00 h(x)` and `h(1x) = 10 h(x)` for all `x` in |?|`? Is `h` an isomorphism? Does
  there exist
> a map `k : ? -> ?` where `k comp h = I_?`, and is `k` one-one?

**Meaning in words.** `h` *spaces the sequence out*: it copies each input symbol `b` and
  inserts a
`0` immediately after it. So the input bit `b` becomes the block `b0`, and `h` doubles the
  length of
  every sequence, planting a `0` in every odd position (0-indexed positions `1, 3, 5, ...`).

We follow the `Example24.runMap` template: a guaranteed-output function on finite prefixes
  drives the
  neighbourhood relation `X h Y <-> exists sigma, X = sigmaSigma* /\ Y in ? /\ (hOut
    sigma)Sigma* subseq Y`.

* `hOut sigma` -- the doubling of `sigma` (each `b` |-> b0`); `hMap : ApproximableMap B B`.
* `kOut tau` -- the left inverse on prefixes: keep the first bit of every *complete* pair, drop
  the
  inserted `0`; `kMap : ApproximableMap B B`. Key identity: `kOut (hOut sigma) = sigma`.
* `kMap_comp_hMap` -- **`k comp h = I_?`** (so the required `k` exists).
* `kMap_not_injective` -- **`k` is *not* one-one**: `(0Sigma)*` and `(1Sigma)*` both map to `
  False` (the first
  bit of a length-1 prefix is an incomplete pair, hence dropped).
* `hMap_not_surjective` -- **`h` is *not* an isomorphism**: it is not surjective (e.g. `(01
  Sigma)*` is
  not in the range, since `h` only produces sequences with `0` in every odd position). `h` *is*
  injective (it has the left inverse `k`), so it is injective-but-not-surjective.

Choice-free (`#print axioms subseq {propt, Quot.sound}`): everything is decidable list
  surgery. -/

# Exercise 2.20 (Scott 1981, PRG-19, S2) -- the powerset domain `?`

```

```

> **EXERCISE 2.20.** Discuss again the example of Exercise 1.15 where the domain turns out to
    be the
> powerset of `Nat`. Show how the finite elements can be taken to be the finite subsets of `Nat`
    and can
> be identified with the tokens of a suitable neighbourhood system `?`. (Hint: Define `F` for
    finite
> sets `F`  $\text{subseq Nat}$ .) Show that both `x U y` and `x I y` are approximable functions
    of two variables, and
> that `x + 1 = {n + 1 ? n in x}` and `x ? 1 = {n ? n + 1 in x}` are approximable.

> Warning: **Numbering note.** Our `Exercise115.lean` formalized the *flat*/stem systems, **
    not** the
> powerset domain; so `?` is built fresh here.

**Token encoding.** We take tokens `Delta = Nat` and let the neighbourhoods of `?` be the **
    cofinite**
subsets of `Nat`. Since the principal-filter map `X |-> X` is inclusion-*reversing*, the
    finite element
`X` represents the finite set `X?`; as `X?` grows (more elements known to be *in* the set), the
    neighbourhood `X` shrinks (more information). Concretely a finite subset `F`  $\text{subseq Nat}$  is
    the finite
element `(F?)`, and `False = Nat` is the empty set.

* `powerSet : NeighborhoodSystem Nat` -- cofinite sets (closed under finite `I`).
* `toSet x := {n ? {n}? in x}` and `ofSet S` -- the identification, packaged as
    **equivSetNat : |?| ?o (Set Nat, subseq) ** (`toSet`/`ofSet` mutually inverse, order-iso
    ).
* `unionMap`, `interMap_2 : ApproximableMap_2 ? ? ?` -- `x U y`, `x I y` (Exercise 2.19),
    with
    `toSet_unionMap`/`toSet_interMap_2` proving the elementwise action is `U`/`I` on `Set Nat`
    .
* `succMap`, `predMap : ApproximableMap ? ?` -- `x + 1`, `x ? 1`, with `toSet_succMap`/`
    toSet_predMap`.

Choice-free (`#print axioms subseq {propext, Quot.sound}`); the `Set.Finite.induction_on`
    in
`mem_compl_of_finite` is structural recursion on a finiteness proof, not `Classical.choice`. -/

Exercise 2.21 (Scott 1981, PRG-19) -- the system ``?``, total finite sequences, juxtaposition

The system ``?`` of 2.3 has as its total elements only the **infinite** sequences: a finite prefix ``sigma``

only ever yields the ***partial*** element ``sigmaFalse = (sigmaSigma*)``, which can always be sharpened by a longer

prefix. We modify ``?`` to a system ``?`` having ***both*** finite and infinite sequences as total elements (Scott's hint ``?` subseq ?``).

The idea: keep the cones ``sigmaSigma* = cone sigma`` of ``?`` (these give the partial ``sigmaFalse`` and, in the limit, the infinite total sequences), and add for every finite ``sigma`` a **terminator token** -- the ***singleton***

``{sigma}``. The neighbourhood ``{sigma}`` asserts "the sequence is exactly ``sigma`` (terminated)".

Because ``{sigma}`` is a minimal nonempty neighbourhood, ``{sigma}`` is a **total** (maximal) element -- this is the total finite

sequence ``sigma``. We thus distinguish:

`* `? = {[]}`` -- the ***total empty sequence*** (terminated), and

`* `False = Delta = (cone [])`` -- the *\*\*undefined sequence\*\**, with ``False ? ?``.

``? = {sigmaSigma*} U {{sigma}}`` is again pairwise nested-or-disjoint (a singleton sits inside a cone exactly

when its string extends the cone's prefix; two distinct singletons are disjoint), so it is a neighbourhood system via ``ofNestedOrDisjoint``, and visibly ``?` subseq ?``.

***Juxtaposition `xy`.* We build ``juxtapose : ApproximableMap_2 ? ? ?`` realizing the left-to-right-biased concatenation:

** if `x` extends the prefix `sigma` but is *not known to terminate* (a cone neighbourhood ``sigmaSigma*`` in `x``),*

*the result only commits to the prefix ``sigma`` -- ``xy ? sigmaFalse``, independent of ``y``. Hence ***for an infinite**

*(total) ``x``, ``xy = x`` for all ``y``** (``juxtapose_cone``);*

** if `x` is the total finite sequence `sigma` (the terminator ``{sigma}`` in `x``), the result is ``sigma`` followed by*

``y``: ``xy`` prepends ``sigma`` to ``y`` (``juxtapose_singleton_mem``).

This is the "strong left-to-right bias" Scott describes: ``y`` is consulted only after ``x`` is known to

have terminated.

# Exercise 2.22 (Scott 1981, PRG-19) -- the abstract representation theorem

(*For set theorists.*) Exercises 1.18 and 2.11 noted that any domain `|?|`, viewed as a family
of
sets, is closed under (i) the intersection of an arbitrary non-empty subfamily and (ii) the
union
of any directed subfamily. This exercise proves the converse: any family `C` of sets with
these
two closure properties is inclusion-isomorphic to a domain.

We follow Scott's hint. Fix `C : Set (Set tau)` (non-empty) closed under non-empty
intersections
(`hInter`) and directed unions (`hDir`).

* `Delta` = the finite sets `F` included in some member of `C` (here the subtype `Tok C`).
* The closure of `F` is `F = ? {X in C ? F subseq X}` (`Cl C F`); since `F` lies in
some member of
`C`, this intersection is over a non-empty family, so `F in C` (`Cl_mem`). The `F` are the
"finite"
elements.

```

```

* The neighbourhood system `reprSystem` over `Delta` has neighbourhoods `C(F) = {G in Delta ?
  F subseq G}`
  (`nbhd C F`).

The representation isomorphism `reprIso : reprSystem.Element ?o C` (under `subseq`) sends
  an ideal element
`x` to `{F ? C(F) in x}` and a set `X` in `C` to the element generated by `{C(F) ? F
  subseq X}`. The key
identity (Scott) is `X = ? {F ? F subseq X, F in Delta}`, realized by `toC_ofC`/`
  mem_nbhd_iff`.

**Axioms.** This is the genuinely set-theoretic exercise: it uses `Classical.choice` (picking
  witnesses
of `C.Nonempty`, finite-set induction). This is documented and expected per the exercise's
  framing
("for set theorists").

# Lecture III (S3) -- the product system: Definitions 3.1, 3.3, Propositions 3.2, 3.4,
Lemma 3.6, Theorems 3.5, 3.7

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981),
Lecture III,
*Constructions on domains*. Given two neighbourhood systems over **disjoint** token sets `
Delta_0`, `Delta_1`,
the **product system** `?_0 x ?_1` has neighbourhoods `X U Y` (`X` in `?_0`, `Y` in `?_1`)
over `Delta_0 U Delta_1`.

We model the disjoint union of token sets by the **sum type** `a ? b`, and the product
neighbourhood `X U Y` by `prodNbhd X Y = Sum.inl '' X U Sum.inr '' Y`. Because `Sum.inl`
and
`Sum.inr` have disjoint ranges, the cleanest facts of Scott's proof become transparent:

* `prodNbhd_inter` -- `(X U Y) ∩ (X' U Y') = (X ∩ X') U (Y ∩ Y')` (Scott's (2));
* `prodNbhd_subset_iff` -- `X U Y ⊆ X' U Y' <=> X ⊆ X' /\ Y ⊆ Y'` (Scott's (1));
* `prodNbhd_injective` -- the representation `X U Y` is unique.

This file formalizes:

* **Definition 3.1 / Proposition 3.2** -- the product system `prod V_0 V_1`, the element
pairing
`pair x y = <x, y>`, the order law `pair_le_pair_iff` (3.2(i)), and the order-isomorphism
`prodEquiv : |?_0 x ?_1| ≅o |?_0| x |?_1|`.
* **Definition 3.3 / Proposition 3.4** -- projections `proj_0`, `proj_1`, the paired mapping `
paired f g`,
and `proj_0_comp_paired`, `proj_1_comp_paired`, `paired_proj` (`<p_0 comp h, p_1 comp h> = h
`),
`toElementMap_paired` (`<f, g>(w) = <f(w), g(w)>`).
* **Lemma 3.6** -- constant maps `constMap b` (`X b Y <=> Y in b`) with `
toElementMap_constMap`.
* **Theorem 3.5** -- joint vs. separate approximability, via the bridge `ApproximableMap (prod
V_0 V_1) V_2
? ApproximableMap_2 V_0 V_1 V_2` (`ofMap_2` / `toMap_2` and round-trips).
* **Proposition 3.7** -- multivariate approximable functions are closed under substitution
(`comp` / `paired` / `proj` bookkeeping).

Everything is **choice-free** (`#print axioms subseteq {propext, Quot.sound}`).

# Lecture III (S3) -- the function space `(?_0 -> ?_1)`: Definitions 3.8, Propositions 3.9,
Theorems 3.10, 3.11, 3.12, 3.13

```

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981), Lecture III.

The **function space** $(\tau_0 \rightarrow \tau_1)$ is the neighbourhood system whose **tokens** are the approximable maps $\tau_0 \rightarrow \tau_1$ (Definition 2.1), and whose neighbourhoods are the non-empty finite intersections of the **step sets**

$$[X, Y] = \{f \mid X \subseteq f \subseteq Y\} \quad (\text{step } X \ Y),$$

for X in τ_0 , Y in τ_1 . We model a finite intersection by a **List** of (X, Y) pairs, with

$$\text{stepFun } L = \{f \mid \text{forall } (X, Y) \text{ in } L, X \subseteq f \subseteq Y\};$$

the empty list gives the master $\Delta = \tau_0 \rightarrow \tau_1$ (**Set.univ**). The system is **positive**: a neighbourhood is required non-empty, which is exactly what makes a filter's induced relation **interjective** (Theorem 3.10).

This file formalizes:

- Definition 3.8** -- **step**, **stepFun**, the system **funSpace** $V_0 \ V_1$, with the basic algebra
- step_inter_right** ($[X, Y] \cap [X, Y'] = [X, Y \cap Y']$), **step_subset** (antitone/monotone), **step_master_eq** ($[\Delta_0, \Delta_1] = \text{univ}$), and membership **step_mem**.
- Theorem 3.10** (the crux) -- **funSpaceEquiv** : $\tau_0 \rightarrow \tau_1 \mid \exists \text{ ApproximableMap } V_0 \ V_1$: every filter is fixed by a unique approximable map (**toApproxMap**/**toFilter**), inclusion-preservingly.
- Proposition 3.9** -- **leastMap** (the least map f_0 of a consistent neighbourhood, condition (ii) $X \subseteq f_0 \subseteq Y \iff \{Y_i \mid X \subseteq Y_i \subseteq Y\} \subseteq f_0$), **leastMap_mem_stepFun** and **leastMap_le** (it is the minimal element of $\{[X_i, Y_i]\}$), and **stepFun_subset_step_iff** (the remark after 3.9). The consistency hypothesis **hcons** is Scott's condition (i) in operational form.
- Theorem 3.13** -- **le_iff_toElementMap_le** (i); **mapsBounded_iff_pointwiseBounded** (ii); **sSupMaps** with **toElementMap_sSupMaps** (iii).

# Exercise 3.14 (Scott 1981, PRG-19, S3) -- the diagonal map

Scott's Exercise 3.14 makes two points.

* **The disjointness of `Delta_0` and `Delta_1` is unnecessary.** Working over a denumerable
  token alphabet
  `Sigma = {0, 1}`, one may *tag* the two factors, taking the product system over `0Delta_0 U
  1Delta_1` with
  neighbourhoods `0X U 1Y`. Our `Product.lean` already realizes exactly this tagging
  abstractly:
  the disjoint union of token *types* `a ? b` is the type-theoretic incarnation of `0Delta_0 U
  1Delta_1`, and
  `prodNbhd X Y = Sum.inl '' X U Sum.inr '' Y` is `0X U 1Y`. So no separate construction is
  needed --

```

```

`prod V_0 V_1` *is* the tagged product, and the revised pairing ` $\langle x, y \rangle$ ` is `pair` (
  Definition 3.1).

* **The diagonal `diag : ? -> ? x ?`, `diag(x) = <x, x>`.** This is the paired map ` $\langle I, I \rangle$ `
  of the
  identity with itself (Definition 3.3), so it is approximable for free, and
  `toElementMap_diag` computes `diag(x) = <x, x>` from `toElementMap_paired`.

The `n`-fold product ` $\prod_{i=0}^{n-1} x_i$ ` over ` $\Delta_i$ ` is obtained by
  iterating the binary
  `prod` (it is associative up to isomorphism, Exercise 3.15); the binary diagonal here is the
  `n = 2` instance of the general diagonal ` $x \mapsto \langle x, \dots, x \rangle$ '.

Everything is **choice-free** (`#print axioms subseq {proptext, Quot.sound}`).

# Exercise 3.15 (Scott 1981, PRG-19, S3) -- the usual product isomorphisms

Scott asks for the standard isomorphisms of the product construction. Because Proposition 3.2
gives
the order-isomorphism `prodEquiv : |?_0 x ?_1| ?o |?_0| x |?_1|`, every isomorphism reduces
to the
corresponding fact about cartesian products of *ordered sets*: mathlib's `OrderIso.prodComm`
and
`OrderIso.prodAssoc`, together with the two product congruences `prodCongrOrderIso` /
`prodUniqueOrderIso` we record here.

* ** (i) ** `?_0 x ?_1 ~?= ?_1 x ?_0` -- `prodCommD`.
* ** (ii) ** `?_0 x (?_1 x ?_2) ~?= (?_0 x ?_1) x ?_2` -- `prodAssocD`.
* ** The product of no factors ** is the one-point (terminal) domain `? = unitSys`; it is a two-
sided
unit for `x` : `? x ? ~?= ? ~?= ? x ?` (`prodUnitD`, `unitProdD`).
* ** (iii) ** `?_0 ~?= ?_0` and `?_1 ~?= ?_1` imply `?_0 x ?_1 ~?= ?_0 x ?_1` -- `
prodCongrD` /
`Isomorphic.prod`.

Everything is **choice-free** (`#print axioms subseq {propeq, Quot.sound}`).

# Exercise 3.18 (Scott 1981, PRG-19, S3) -- the sum (coproduct) system

Scott's sum of `?_0` (over `Delta_0`) and `?_1` (over `Delta_1`), assuming *no neighbourhood is
empty*:

`?_0 + ?_1 = {{?}} U 0Delta_0 U 1Delta_1 U {0X ? X in ?_0} U {1Y ? Y in ?_1}`,

a neighbourhood system over `{{?}} U 0Delta_0 U 1Delta_1`. We model the tokens as `Option (a
? b)`: `? = none`,
`0a = some (inl a)`, `1b = some (inr b)`; then `0X = il '' X` and `1Y = ir '' Y`.

The non-emptiness assumption (`h_0`, `h_1`) is exactly what makes the system closed under
intersection:

```

the two tagged copies are disjoint ($\text{inj}_0 X \cap \text{inj}_1 Y = \{\}$), so a cross pair $\langle 0x, 1y \rangle$ is *inconsistent* (no non-empty neighbourhood lies in $\{\}$), and same-tag intersections reduce to those of the factors.

We then build the injections $\text{inMap}_i : ?_i \rightarrow ?_0 + ?_1$ and projections $\text{outMap}_i : ?_0 + ?_1 \rightarrow ?_i$, and prove $\text{outMap}_i \circ \text{inMap}_i = \text{I}_{\{?_i\}}$. (The non-emptiness assumption is what makes the system a neighbourhood system; the section/retraction identities hold for the resulting maps.)

Everything is **choice-free** (`#print axioms subseteq {propext, Quot.sound}`).

# Exercise 3.19 / 3.20 (Scott 1981, PRG-19, S3) -- the product functor `f x g`

Given approximable mappings `f : ?_0 -> ?_0'` and `g : ?_1 -> ?_1'`, Scott's Exercise 3.19
constructs
the product mapping `f x g : ?_0 x ?_1 -> ?_0' x ?_1'` with

* **(i)** `(f x g)(<x, y>) = <f(x), g(y)>`, and
* ** (ii)** `f x g = <f comp p_0, g comp p_1>`.

We take (ii) as the definition (`prodMap`, built from Definition 3.3's `paired`/`proj`), and
prove
(i) -- indeed the more general `toElementMap_prodMap` (`(f x g)(w) = <f(w_0), g(w_1)>`).

Exercise 3.20 (for category theorists) then follows: `x` is a functor (`prodMap_id`,
`prodMap_comp`), and `prod` with its projections is the categorical product -- the
universal
property `paired`/`proj` with uniqueness `paired_unique`.

The sum functor `f + g` is treated in `Exercise318.lean`/`Exercise319Sum.lean` after the sum
system
is built. Everything here is choice-free (`#print axioms subseq {propeq, Quot.sound}`)
.

# Exercise 3.19 (Scott 1981, PRG-19, S3) -- the sum functor `f + g`

Given approximable mappings `f : ?_0 -> ?_0'` and `g : ?_1 -> ?_1'`, Scott's Exercise 3.19
also asks for the

```

sum mapping $f + g : ?_0 + ?_1 \rightarrow ?_0' + ?_1'$, characterized (equations (iii), (iv)) by

```
* `out_0 comp (f + g) comp in_0 = f`, and
* `out_1 comp (f + g) comp in_1 = g`.
```

We build $f + g$ (`sumMap`) directly as a relation between sum-neighbourhoods: it routes the left copy

``0X`` through `f`` (to ``0Y``), the right copy ``1Y`` through `g`` (to ``1Y``), and sends everything to the

master neighbourhood `{?} U 0Delta_0' U 1Delta_1'`. The disjointness of the two tagged copies (Exercise 3.18) is

exactly what makes this a well-defined approximable mapping -- a left input can never produce a right-tagged output, so there is no cross-contamination through `g(False)``.

Scott also asks whether (iii), (iv) *uniquely* determine $f + g$: they do *not*, because the behaviour

on the basepoint ``?`` (i.e. `(f + g)(False)``) is unconstrained; our choice sends ``?`` to ``?``.

Everything is *choice-free* (`#print axioms subseq {propext, Quot.sound}``).

# Exercise 3.21 (Scott 1981, PRG-19, S3) -- when does `[Y, Z]` determine `Y` and `Z`?

In the proof of Theorem 3.12 it is tacitly assumed that the function-space neighbourhood `[Y, Z]`
(the set `step Y Z = {f ? Y f Z}` of approximable mappings) uniquely determines its endpoints `Y`, `Z`.
Scott's Exercise 3.21 asks to make this precise.

* **If `Z != Delta_2`** the pair is determined: `[Y, Z] = [Y', Z']` forces `Y = Y'` and `Z = Z'`
  (`step_eq_of_ne_master`). The hint is to use the least element of `[Y, Z]` -- here the
  single-step
  map `leastMap [(Y, Z)]` of Proposition 3.9.
* **If `Z = Delta_2`** then `[Y, Delta_2] = [?_1 -> ?_2]` is the whole space for every `Y`
  (`step_master_right`),

```

```

so `Y` is not determined; nevertheless the biconditional of Theorem 3.12 stays valid because
`Delta_1 g Delta_2` always holds.
* **General criterion** (`step_eq_iff`): `[Y, Z] = [Y', Z']` iff either both outputs are `
Delta_2`, or
`Y = Y'` and `Z = Z'`.

Everything is **choice-free** (`#print axioms subseq {propt, Quot.sound}`).

# Exercise 3.22 (Scott 1981, PRG-19, S3) -- composition is approximable

Scott asks for the approximable composition mapping

`comp : (?_1 -> ?_2) x (?_0 -> ?_1) -> (?_0 -> ?_2)`, `comp(g, f) = g comp f`,

and suggests building it from `eval` and `curry`. We follow the hint: the uncurried form

`compApp : ((?_1 -> ?_2) x (?_0 -> ?_1)) x ?_0 -> ?_2`, `compApp(<<g, f>, x) = g(f(x))`,

is assembled from the two evaluation maps and the projections/pairing of Definition 3.3, and
then
`compMap = curry compApp` is the desired map. Theorem 3.12's `toElementMap_curry_apply` and
3.11's
`evalMap_apply` compute `comp(g, f) = g comp f` on elements (`toElementMap_compMap_apply`).

Everything is choice-free (`#print axioms subseq {proptext, Quot.sound}`).

# Exercise 3.23 (Scott 1981, PRG-19, S3) -- the category of domains is cartesian closed

Exercise 3.23 asks (for category theorists) to read off from Theorems 3.11 and 3.12 that the
category
of domains and approximable mappings is *cartesian closed*, to identify its terminal object,
and to
say what sort of functor  $(?_0 \rightarrow ?_1)$  is.

The three ingredients are already in the development; this file packages them and supplies the
missing terminal object:

* Terminal object. The one-point domain  $? = \text{unitSys}$  (Exercise 3.15) is *terminal*: there
is a
unique approximable mapping  $? \rightarrow ?$  ( $\text{Unique (ApproximableMap V unitSys)}$ ), because  $|?|$ 
is a
subsingleton.
* Finite products.  $\text{`prod`}$  with  $\text{`proj_0`}$ ,  $\text{`proj_1`}$  is the categorical product (Exercise
3.20).
* Exponentials.  $\text{`curryEquiv`}$  (Theorem 3.12) is the natural adjunction
 $\text{`Hom}(?_0 \times ?_1, ?_2) \cong \text{Hom}(?_0, (?_1 \rightarrow ?_2))$ , exhibiting  $(?_1 \rightarrow ?_2)$  as the
exponential  $?_2^{?_1}$ .

```

```

So `?`, `x`, and `→` make the category cartesian closed, and `(α₀ → α)` is a (
  covariant) functor
right adjoint to `x α₀`. Everything is choice-free (#print axioms subseq {propext
  , Quot.sound}).

# Exercise 3.24 (Scott 1981, PRG-19, S3) -- function-space isomorphisms

Scott asks to establish further isomorphisms. We formalize (i):

 $(\alpha_0 \rightarrow (\alpha_1 \times \alpha_2)) \cong (\alpha_0 \rightarrow \alpha_1) \times (\alpha_0 \rightarrow \alpha_2)$ .

The crux is the order-isomorphism on the approximable maps themselves,
`funProdEquiv : Hom( $\alpha_0$ ,  $\alpha_1 \times \alpha_2$ )  $\cong$  Hom( $\alpha_0$ ,  $\alpha_1$ )  $\times$  Hom( $\alpha_0$ ,  $\alpha_2$ )`, given by
`h |-> (p_0 comp h, p_1 comp h)` with inverse ` $\langle a, b \rangle$  |->  $\langle a, b \rangle$ ` (Definition 3.3's `
  paired`/`proj`, and the
round-trips `paired_proj` / `proj_comp_paired`. Transporting through Theorem 3.10's `
  funSpaceEquiv`
and Proposition 3.2's `prodEquiv` gives the domain isomorphism `funProdIso`.

Everything is choice-free (`#print axioms subseteq {propeq, Quot.sound}`).

# Exercise 3.16 (Scott 1981, PRG-19, S3) -- the infinite iterate `?^ inf`

Scott: for a neighbourhood system `?` over `Delta`, let `Delta^ inf = ?_n 1?0Delta` be
infinitely many disjoint
copies of `Delta`, and let `?^ inf` be the least family of subsets with

1. `Delta^ inf` in `?^ inf`, and
2. `X` in `?`, `Y` in `?^ inf` `?` `0X U 1Y` in `?^ inf`.

He asks to show `?^ inf` is a neighbourhood system over `Delta^ inf`, that `?^ inf ~= ? x
?^ inf`, and that the
elements of `|?^ inf|` are in one-one correspondence with arbitrary infinite sequences ``
of
elements `x_n` in `|?|`, via the combinations of neighbourhoods

`0X_0 U 10X_1 U ? U 1?0X_n U ?` (with all but finitely many `X? = Delta`).

**Model.** We take the token type to be `Nat x a`, where `(n, a)` is "the token `a` in `Delta`
sitting in
the `n`-th copy" (i.e. Scott's `1?0a`). A neighbourhood `0X_0 U 1?0X_n U ?` is then exactly
the set
`{(i, a) ? a in X_i}`, recovered from `W` by its fibers `fiber W i = {a ? (i, a) in W
}`. The
"least family" description is equivalent to: `W` in `?^ inf` iff every fiber is a
neighbourhood and all
but finitely many fibers equal `Delta`. (Closure under (2) and the base (1) generate exactly
these, and
no fewer, because (2) is the one-step "cons" and the cofinite-`Delta` condition is its iterate
.)

The element-level payoff is the clean order-isomorphism

`iterSeqEquiv : |?^ inf| ?o (Nat -> |?|)`

(Scott's "one-one correspondence with infinite sequences"), from which `?^ inf ~= ? x ?^
inf` falls out by
the shift `(Nat -> E) ?o E x (Nat -> E)`.

```

Everything is ****choice-free in spirit****; the classical content is only what is inherited from the project's ``Element.ext`/`prodEquiv`` machinery, as elsewhere in S3.

# Exercise 3.17 (Scott 1981, PRG-19, S3) -- `B` is a retract of  $T^\infty$ 

Using the binary system `B` (Example 1.B) and the three-element truth system `T` (Example 1.2),
Scott asks for a one-one approximable map  $f : B \rightarrow T^\infty$  and a map  $g : T^\infty \rightarrow B$  with

 $g \circ f = I_B$  and  $f \circ g \sqsubseteq I_{T^\infty}$ ,

i.e. `B` is a retract of  $T^\infty$  ( $f$  a section,  $g$  a retraction). He then asks whether  $B \simeq T^\infty$ 
and  $B \simeq T \times B$  (the point of the exercise being that  $\text{retract} \neq \text{isomorphism}$  here).

The encoding. A binary string  $\sigma = b_0b_1\dots b_{k-1}$  (a neighbourhood  $\sigma\text{Sigma}$  of
`B`) is sent to the
 $T^\infty$ -neighbourhood  $\text{encSet } \sigma$  that pins copy `i` to the truth value  $\text{bitNbhd } b_i$ 
(`{0}` for `false`,
`{1}` for `true`) for  $i < k$ , and leaves copies  $i \geq k$  free ( $\Delta_T$ ). Concretely
 $\text{encSet } \sigma$  is the
pointwise set  $\{(i, t) \mid \forall b, \sigma[i] = \text{some } b \rightarrow t \in \text{bitNbhd } b\}$ .

`f` relates  $\sigma\text{Sigma}$  to every  $T^\infty$ -neighbourhood weaker than  $\text{encSet } \sigma$ ;
`g` relates a  $T^\infty$ -neighbourhood `W` to  $\tau\text{Sigma}$  exactly when  $W \subseteq \text{encSet } \tau$ ,
i.e. `W` already pins
the first  $|\tau|$  copies to  $\tau$  (decoding the longest gap-free prefix).

 $g \circ f = I_B$  ( $\text{gf\_eq\_id}$ ) -- decoding recovers the prefix, the key being
 $\text{prefix\_of\_encSet\_subset}$  ( $\text{encSet } \sigma \subseteq \text{encSet } \tau \rightarrow \sigma \preceq \tau$ ), which uses that
 $T^\infty$ -neighbourhoods are
non-empty.  $f \circ g \sqsubseteq I_{T^\infty}$  ( $\text{fg\_le\_id}$ ) holds because re-encoding a decoded
element can only lose
the post-gap information. Hence `f` is one-one ( $\text{f\_injective}$ ).

/-.!
# Exercise 3.24(ii) (Scott 1981, PRG-19, S3) -- `(?_0 -> ?_1^inf) ~= (?_0 -> ?_1)^inf`

Using the infinite iterate `?^inf` of Exercise 3.16 and the function space `(?_0 -> ?_1)`
of
Definition 3.8 / Theorem 3.10, we establish Scott's isomorphism (ii):

`(?_0 -> ?_1^inf) ~= (?_0 -> ?_1)^inf`.

The crux is the order-isomorphism *on approximable maps*

`funIterEquiv : Hom(?_0, ?_1^inf) ?o (Nat -> Hom(?_0, ?_1))`,

`f |-> (n |-> proj_n comp f)` with inverse the "infinite pairing" `g |-> mapOfSeq g`,
whose value is the
sequence `mapOfSeq g (x) = <g_n(x)>_n`. Transporting through Theorem 3.10's `funSpaceEquiv` (
twice,
the second time pointwise via `OrderIso.piCongrRight`) and Exercise 3.16's `iterSeqEquiv`
yields the
domain isomorphism.

```

```

Everything is **choice-free in spirit**; the only classical input is inherited from `Element.
  ext`,
`funSpaceEquiv` and the `choose` in the `exists /forall`-swap lemma, exactly as elsewhere in
S3.

import Scott1980.Neighborhood.Product

/-.!
# Exercise 3.24(iii)(iv) (Scott 1981, PRG-19, S3) -- sum/product "isomorphisms" that are only
  maps

Scott's list of isomorphisms ends with two entries and the caveat *"If some of the above are
  not
true, perhaps at least some mapping relationships can be established."* Parts (iii) and (iv)
  are
exactly those: with Scott's separated sum  $?_0 + ?_1$  (a fresh bottom  $?^$  glued below two
  disjoint
copies), neither

* (iii)  $?_0 \times (?_1 + ?_2) \approx (?_0 \times ?_1) + (?_0 \times ?_2)$ , nor
* (iv)  $?(?_0 + ?_1) \rightarrow ?_2 \approx (?_0 \rightarrow ?_2) \times (?_1 \rightarrow ?_2)$ 

holds as a genuine isomorphism. (For (iv):  $\text{in}_i(\text{False})$  lies strictly above the sum's bottom,
  so a map
 $h$  is not recoverable from  $h \text{ comp } \text{in}_0$  and  $h \text{ comp } \text{in}_1$  -- the value  $h(\text{False})$  is
  free. For (iii): the
left side has, for each  $x$  in  $|?_0|$ , an element  $\langle x, \text{False} \rangle$  incomparable to both cones,
  which the right
side lacks.)

What is true are the canonical mapping relationships:

* (iv) the copairing  $[a, b] : ?_0 + ?_1 \rightarrow ?_2$  with  $[a, b] \text{ comp } \text{in}_i = a, b$  ( $\text{copair}$ ,
   $\text{copair\_comp\_inMap}_0/_1$ ), exhibiting  $?(?_0 \rightarrow ?_2) \times (?_1 \rightarrow ?_2)$  as a retract of  $?(?_0 + ?_1) \rightarrow ?_2$ 
  ( $\text{copairProj\_copair}$ ); and
* (iii) the canonical distribution map
   $?(?_0 \times ?_1) + (?_0 \times ?_2) \rightarrow ?_0 \times (?_1 + ?_2)$  ( $\text{distribMap}$ ),  $\text{in}_i \langle x, u \rangle \mapsto \langle x, \text{in}_i u \rangle$ .

The development re-uses Exercise 3.18's injections/projections and the structural extraction
  lemmas of
Exercise 3.19.

# Exercise 3.25 (Scott 1981, PRG-19, S3) -- the open sets of `|?|` form a domain

(*For topologists.*) Exercises 1.21/1.22 and 2.13 regard a domain `|?|` as a topological space
(the
basic opens `[X] = {x ? X in x}`, `basicOpen`) on which the approximable maps are exactly the
continuous functions. Scott asks, "using 3.10", to show that the family of open subsets of
`|?|`
is isomorphic to a domain.

The route is the standard "open sets = maps to Sierpinski space". Let `?` be the Sierpinski
domain (`sierpinski`): the two-token-state system whose neighbourhoods are `Delta = univ` and
`{}`, so
`|?|` is the two-element domain `False ? top`. The correspondence

* `mapOfOpen U` : `? -> ?`, relating `X` to `{X}` (the "defined"/top neighbourhood of `?`)
exactly when
`[X] subseteq U`, and to `univ` always;
* `openOfMap f = {x ? f(x) = top} = ? {[X] ? X f {X}}`;

are mutually inverse and inclusion-preserving (`openIso`), so by Theorem 3.10 (`
funSpaceEquiv`,
`|? -> ?| ? ApproximableMap`) the lattice of open sets is order-isomorphic to the domain

```

```

`|? -> ?|` (`opensReprIso`). The one place topology (openness of `U`) is used is the round
trip
`openOfMap (mapOfOpen U) = U` and the `<-` half of order reflection: an open set is recovered
from its
basic neighbourhoods.

# Exercise 3.27 (Scott 1981, PRG-19, S3) --  $|?_0 \rightarrow ?_1|$  is a domain, via Exercise 2.22

(*For set theorists.*) Scott asks for another proof that the family of approximable mappings
 $f : ?_0 \rightarrow ?_1$  is isomorphic to a domain, "by employing the general argument of Exercise
2.22"
(the abstract representation theorem: any family of sets closed under non-empty intersections
and
directed unions is inclusion-isomorphic to a domain).

The set-theoretic content: identify each approximable map  $f$  with its graph

```

```

`graph f = {(X, Y) ? X f Y} subseq ?(Delta_0) x ?(Delta_1)`, and let `C = {graph f}` be
the family of all such
graphs. Then

* `C` is closed under non-empty intersections -- the pointwise meet ` /\ ` of a family
of
approximable maps (relate `X` to `Y` iff every member does) is again approximable (`meetMap`)
;
* `C` is closed under directed unions -- the join ` \/ ` of a directed family (relate `
X` to `Y`
iff some member does) is again approximable, the consistency condition using directedness
(`joinMap`).

So Exercise 2.22 (`reprIso`) re-presents `C` -- hence, via `graph` and Theorem 3.10 (`
funSpaceEquiv`),
the whole function space `|?_0 -> ?_1|` -- as the domain of a neighbourhood system, without
writing
down the step-set neighbourhoods of Definition 3.8 explicitly. This is exactly Scott's "compare
with
3.9/3.10" alternative.

Axioms. As flagged by Scott ("for set theorists"), this inherits `Classical.choice` from
Exercise 2.22 and from the `graph`-inversion.

/-!
# Exercise 3.26 (Scott 1981, PRG-19, S3) -- the conditional operator `cond`

Scott asks: for every domain `D` there is an approximable mapping

`cond : T x D x D -> D`

(the *conditional operator*) satisfying

* `cond(true, x, y) = x`,
* `cond(false, x, y) = y`,

```

```
* `cond(False,      x, y) = False`.
```

Here T is the truth domain of Example 1.2 (`Example12.neighborhoodSystem`), whose neighbourhoods are $\{\Delta, \{0\}, \{1\}\}$ with $\text{true} = \{0\}$ (`Example23.trueElt`), $\text{false} = \{1\}$ (`falseElt`) and $\text{False} = \{\Delta\}$ (`botElt`). The product $T \times D \times D$ is the tagged product of Exercise 3.14, modelled here as `prod T (prod V V)` over the token type `T.Token ? (a ? a)`; a neighbourhood is `OC U 10X U 110Y`, recovered from `W` by the projections $C = \text{inl}^{-1} W$, $X = \text{inl}^{-1} \text{inr}^{-1} W$, $Y = \text{inr}^{-1} \text{inr}^{-1} W$.

Scott's hint gives the relation directly:

```
...
OC U 10X U 110Y cond Z iff 0 in C and X subseq Z, or
                           1 in C and Y subseq Z, or
                           0, 1 in C and Delta subseq Z.
...
```

Since $T = \{\Delta, \{0\}, \{1\}\}$, the three guards on C are **mutually exclusive and exhaustive**: $0 \text{ in } C$ (alone) means $C = \{0\}$, $1 \text{ in } C$ (alone) means $C = \{1\}$, and $0, 1 \text{ in } C$ means $C = \Delta$. We therefore phrase the relation with explicit equalities $C = \{0\} / \{1\} / \Delta$ (`condGuard`), which is mathematically identical to Scott's membership form but makes the case analysis transparent and the three identities clean.

Everything is ***choice-free*** in spirit; the only classical input is inherited from T (Example 1.2) and from the project's `ext_of_toElementMap`/`Element.ext` machinery, as elsewhere in S3.

# Exercise 3.26, continued (Scott 1981, PRG-19, S3) -- the sum-valued conditional and `which`

```

This module completes Exercise 3.26 with the two follow-up operators Scott asks for:

```
* the sum-valued conditional `condSum : T x D_0 x D_1 -> D_0 + D_1`, routing `true
  -> in_0`,
  `false -> in_1`, `False -> False`. It is obtained for free by *composition*: feeding the
  two inputs through
  the injections `in_0, in_1` into the common domain `S = D_0 + D_1` and then applying the
  conditional
  `cond S : T x S x S -> S` of Exercise 3.26. The three identities follow from `cond_true
  /false/bot`.

* the discriminator **`which : D_0 + D_1 -> T`** reading the tag (`0X |-> true`, `1Y |->
  false`,
  `? |-> False`), together with Scott's identity

  `cond(which x, in_0(out_0 x), in_1(out_1 x)) = x` for all `x in |D_0 + D_1|`.
```

The discriminator is built directly as a neighbourhood relation; its three guards on the truth component are mutually exclusive because the three forms of a sum-neighbourhood (``?-master``, `left` copy, right copy) are mutually exclusive (Exercise 3.18, using non-emptiness).

# Exercise 3.28 (Scott 1981, PRG-19, S3) -- the elementwise formula for the least map

In `(?_0 -> ?_1)`, let `{[X_i, Y_i] ? i < n}` be a non-empty neighbourhood. Proposition 3.9
characterizes its minimal element `f_0` as a *relation* (`leastMap`, `X f_0 Y <-> {Y_i ? X
  subseq X_i} subseq Y`).
Exercise 3.28 asks for the **elementwise** description:

`f_0(x) = sqsup { Y_i ? x in [X_i] }` for `x in |?_0|`,

where `x in [X_i]` means `X_i in x` (the input is at least as defined as `X_i`). We
formalize this as
`toElementMap_leastMap_eq_sqsup`: `f_0(x)` is the least upper bound (Exercise 1.27's `sSup`) of
the
principal filters `Y_i` over the active indices.

The proof shows `f_0(x)` is *the* least upper bound of that set: it is an upper bound
(`val_le_leastMap_toElementMap`, from `Y_i in f_0(x)`), and it is least
(`leastMap_toElementMap_le_of_ub`, because any upper bound contains every relevant `Y_i`, hence
the
finite intersection `{Y_i ? X subseq X_i}`); the equality with `sqsup` then follows by
antisymmetry.

Everything is **choice-free** (`#print axioms subseq {proptext, Quot.sound}`).

# Lecture IV (S4) -- fixed points and recursion: Theorems 4.1 and 4.2

Following Dana Scott, Lectures on a Mathematical Theory of Computation, PRG-19 (1981),
Lecture IV,
*Fixed points and recursion*. The heart of the matter is the **Fixed-point Theorem**:

* **Theorem 4.1** -- every approximable mapping  $f : ? \rightarrow ?$  has a *least* element  $x$  in
 $|?|$  with
 $f(x) = x$ . Scott constructs  $x = \{X \text{ in } ? \mid \Delta f? X \text{ for some } n\}$ , the family of
neighbourhoods
reachable from the master  $\Delta$  along finitely many  $f$ -steps. We model the  $n$ -fold
composition
 $f^n$  by iterMap f n ( $f^0 = I$ ,  $f^{n+1} = f \circ f^n$ ) and the fixed point by fixElement f.
The fixed-point equation is toElementMap_fixElement; minimality among *pre-fixed* points
( $f(z) \subseteq z \implies x \subseteq z$ ) is fixElement_le_of_toElementMap_le.

* **Theorem 4.2** -- the operator  $\text{fix} : (? \rightarrow ?) \rightarrow ?$  is itself approximable. We build it
as
fixMap V : ApproximableMap (funSpace V V) V via the extension-from-finite-elements
principle
(Exercise 2.8, ofMono), sending the finite element  $F$  to  $\text{fix}(F)$  where  $F = \text{leastMap}$  is
the least map of the neighbourhood  $F$  (here toApproxMap (F)). The defining computation
fixMap.toElementMap phi = fix(toApproxMap phi) is Scott's equation (?)
 $\text{fix}(f) = \{ \text{fix}(F) \mid f \text{ in } [F] \}$  (fixMap_toElementMap), whose non-trivial half -- every
finite  $f$ -chain factors through one finite approximant  $F$  in  $\text{phi}$  -- is exists_principal_iterMap.
Then (i)  $\text{fix}(f) = f(\text{fix}(f))$  (fixMap_fixed); (ii)  $f(x) \subseteq x \implies \text{fix}(f) \subseteq x$ 
(fixMap_least);
(iii)  $\text{fix}(f) = \sqsup_n f^0(\Delta)$  (fixMap_eq_iSup, with iterElem_eq_iterate giving the
faithful
 $\sqsup_n f^0(\Delta)$  form); and uniqueness (fixMap_unique).

All *data* constructions (iterMap, fixElement, iterElem, fixMap) are **choice-free**
(#print axioms subseteq {propeq, Quot.sound}); the uniqueness lemma fixMap_unique pulls
Classical.choice only through the project's ext_of_toElementMap, as permitted.

# Example 4.3 (Scott 1981, PRG-19, S4) -- the natural-number domain `N`

Scott's "THE domain of integers" (pages 57-61). The tokens are `Nat`, and the neighbourhoods
are

`N = {{n} ? n in Nat} U {Nat}`

-- a *flat* domain: the singletons `{n}` are the finite total elements and the whole space `Nat`
is the least-informative neighbourhood `Delta = False`. We build `N` by the nested-or-disjoint
criterion
(`ofNestedOrDisjoint`): any two neighbourhoods are nested (one is `Nat`) or disjoint (distinct
singletons).

The (ideal) elements of `|N|` are exactly: the bottom `False = {Nat}` ("undefined"), and for
each `n`

```

```

the total element `n = {n} = {{n}, Nat}` (`natElem n`). Scott then equips `N` with the
  structure
maps

* `succ, pred : N -> N`      (`succMap`, `predMap`)
* `zero : N -> T`           (`zeroMap`, into the truth domain `T` of Example 1.2),

making `` "THE domain of integers". All three are strict approximable
maps determined by their action on the finite total elements:

* `succ(n) = (n+1)`,          `succ(False) = False`;
* `pred((n+1)`) = n`, `pred(0) = False`, `pred(False) = False`;
* `zero(0) = true`, `zero((n+1)`) = false`, `zero(False) = False`.

We capture the common shape -- a map `N -> V` sending `n |-> val n` and `False |-> False`
  -- once and for all in
the combinator `constLiftN`, whose computation rules `constLiftN_natElem`/`constLiftN_bot` give
  all
of the displayed equations uniformly. The data (`N`, `constLiftN`, `succMap`, `predMap`) is
**choice-free** (`#print axioms subseteq {propext, Quot.sound}`); `zeroMap` inherits `
  Classical.choice`
structurally from the truth domain `T` of Example 1.2 exactly as `Example23.parityMap` does.

/-! ### The strict lifting combinator `n |-> val n`, `False |-> False`. -/

/-- The *strict* approximable map `N -> V` determined by a choice of value `val n` in `|V|`
for each
`n`: it sends the total element `n` to `val n` and the bottom `False` to `False`. The relation
`X f Y` holds when either `X = Delta_N` forces the blunt output `Y = Delta_V` (the strict `
False |-> False` clause),
or `X = {n}` and `Y` is a neighbourhood of `val n`.

Definition 2.1 checks uniformly: (i) `Delta_N f Delta_V`; (ii) intersect outputs -- distinct
inputs are
impossible (`Nat != {n}`, singletons are one-one), so both outputs come from the *same* `val
n` and
`inter_mem` of the filter `val n` applies; (iii) sharpening `{n} subseq X` keeps the input
a singleton
`{n}`, and `up_mem` of `val n` widens the output, while a blunt input `Delta_N` forces `Delta_V
`. -/

# Example 4.4 (Scott 1981, PRG-19, S4) -- the domain `C` of binary sequences

Scott's domain `C` of *finite or infinite binary sequences* (pages 61-64), a generalization of
the
natural-number domain `N` of Example 4.3. Over the tokens `Sigma* = List Bool` (Scott's `Sigma
= {0,1}`,
`? = []`), recall the cones `cone sigma = sigmaSigma*` of Example 1.B. The system `C` adds the
*singletons*:

`C = {sigmaSigma* ? sigma in Sigma*} U {{sigma} ? sigma in Sigma*}`.

The total elements correspond to finite or infinite sequences: `sigma = {sigma}` (`strElem
sigma`, the finite
sequence `sigma` *completed*) and `sigmaFalse = sigmaSigma*` (`strBot sigma`, the partial
element "starts with `sigma`"). `C`
is again nested-or-disjoint, so it is a neighbourhood system (`ofNestedOrDisjoint`).

We equip `C` with the two **successors** `x |-> 0x` and `x |-> 1x` (`consMap false`, `
consMap true`),
prepending a bit, with their action on the finite/partial elements (`consMap_strElem`,
`consMap_strBot`). As Scott's illustration that recursion now lives inside `|C|`, we then
define the
alternating sequence `a = 01a` as the least fixed point of `x |-> 0(1x)` (`altElt`, `
altElt_eq`),
using the Fixed-point Theorem 4.1.

The remaining structure maps Scott lists for `<C, ?, 0, 1, tail, empty, zero, one>` -- the

```

predecessor analogue ``tail`` (``tail(0x) = tail(1x) = x``, ``tail(?) = False``) and the three tests ``empty``, `zero`, `one : C -> T` -- are exactly the parts Scott leaves as exercises ("It is left to the reader to show that `**tail**` exists as an approximable mapping"; "it is an exercise to show these are approximable", Exercise 4.19); they are out of scope for this module.

The data constructions (``C``, ``consMap``) are **choice-free** (``#print axioms subseq {propext Quot.sound}``).

# Lecture IV (S4) -- Definition 4.5 and Theorem 4.6: models of Peano's Axioms

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981),
Lecture IV, *Fixed points and recursion*, pages 65-66.

* **Definition 4.5** -- a *model for Peano's Axioms* is a structured set  $\langle N, 0, ^+\rangle$  (a type  $N$ 
with a distinguished element  $0 : N$  and a unary `successor`  $^+ : N \rightarrow N$ ) satisfying:
(i)  $0 \neq n^+$  for all  $n$ ; (ii)  $n^+ = m^+ \rightarrow n = m$  (the successor is injective);
(iii) **induction**: whenever  $x \subseteq N$  has  $0 \in x$  and  $x^+ \subseteq x$ , then  $x = N$ .
We package this as `PeanoModel`, stating (iii) in the equivalent point form
 $0 \in s \rightarrow (\forall n \in s, n^+ \in s) \rightarrow \forall n, n \in s \rightarrow (x^+ \subseteq x \rightarrow \forall n \in x, n^+ \in x; x = N)$ 
is  $\forall n, n \in x$ .

* **Theorem 4.6** -- *all models of Peano's Axioms are isomorphic* (`peano_models_isomorphic`).
Scott's proof is an application of the **Fixed-point Theorem 4.1**: between models
 $\langle N, 0, ^+\rangle$  and  $\langle M, [], \# \rangle$  he forms, on the powerset domain  $P(N \times M)$ , the approximable
operator  $u \mapsto \{(0, [])\} \cup \{(n^+, m\#) \mid (n, m) \in u\}$  and takes its **least fixed point**
`r`.

We realize that least fixed point directly as the inductively generated relation `Graph`
(the least set of pairs containing  $(0, [])$  and closed under  $(n, m) \mapsto (n^+, m\#)$  --
exactly the
least fixed point of Scott's monotone operator, by Theorem 4.1). Scott's two facts
(i)  $0 \text{ r } []$  and (ii)  $n \text{ r } m \rightarrow n^+ \text{ r } m\#$  are the two constructors. We then show `Graph` is a
one-one correspondence: functionality + totality on the right (`exists_unique_right`, by
induction 4.5(iii) using 4.5(i)/(ii) to invert the generating rules) and, by the symmetry of
the construction, on the left (`exists_unique_left`). This yields the structure-preserving
bijection  $e : N \rightarrow M$  with  $e 0 = []$  and  $e (n^+) = (e n)\#$ .

All of the *content* (the relation `Graph`, the uniqueness lemmas) is **choice-free**
(`#print axioms subseteq {propext, Quot.sound}`); only the packaging of the bijection  $N \rightarrow M$ 
from the
functional-and-total relation pulls `Classical.choice`, exactly as a Dedekind/recursion theorem
must.

# Exercise 4.7 (Scott 1981, PRG-19, Lecture IV)

Formula 4.2(iii) gives the least fixed point  $\text{fix}(f) = \text{sqsup\_n } f?(False)$ . Suppose instead
that
`a` in  $|?|$  satisfies  $a \sqsub f(a)$ . Will there be a fixed point  $x = f(x)$  with  $a \sqsub x$ ?

**Yes.** Replace  $False$  by  $a$ : the chain  $a \sqsub f(a) \sqsub f?(a) \sqsub \dots$  is
increasing (monotonicity of  $f$ 
applied to  $a \sqsub f(a)$ ), hence directed, so its union  $x = \text{sqsup\_n } f?(a)$  is a genuine
element of  $|?|$ 
(Scott's hint: this is why  $\text{sqsup}$  makes sense -- directed unions of filters are filters,
Exercise 2.11 /
 $\text{iSupDirected}$ ). Approximable maps preserve directed unions ( $\text{toElementMap\_iSupDirected}$ ),
which makes
 $x$  a fixed point, and  $a = f?(a) \sqsub x$  by construction. Moreover  $x$  is the least fixed
point above
 $a$  ( $\text{fixAbove\_least}$ ), the relativized analogue of 4.2(iii).

All constructions are choice-free ( $\text{\#print axioms subseq \{propeq, Quot.sound\}}$ ).

# Exercise 4.8 (Scott 1981, PRG-19, Lecture IV) -- the principle of fixed-point induction

Suppose `f : ? -> ?` and a predicate `S` subseq |?| satisfy

    (i)  `False` in `S`;
    (ii) `x` in `S`  $\Rightarrow$  f(x) in `S`;
    (iii) `S` is closed under sups of increasing sequences.

Then fix(f) in `S`. Since fix(f) = sqsup _n f?(False) (Theorem 4.2(iii)), and f?(False) = False in `S` with the
inductive step f?(False) in S  $\Rightarrow$  f^(n+1)(False) in `S` from (i)/(ii), every approximant lies
in `S`; the
directed union then lies in `S` by (iii). This is fixed-point induction (fix_induction).

As Scott suggests, we apply it to S = {x ? a(x) = b(x)} (fix_induction_eq): if a, b : ?
-> ?
are approximable with a(False) = b(False), f comp a = a comp f and f comp b = b
comp f, then
a(fix f) = b(fix f). (i) is a(False) = b(False); (ii) uses the commutation a(f x) = f(a x)
,
b(f x) = f(b x); (iii) is continuity (a, b preserve directed unions, toElementMap_iSupDirected).

The induction principle is choice-free (#print axioms subseq {propeq, Quot.sound});
the equality
corollary inherits Classical.choice only through the Element extensionality used to compare
the
two directed unions.

# Exercise 4.9 (Scott 1981, PRG-19, Lecture IV) -- the operator `?` and `fix = fix(?)`

Scott asks for an *approximable* operator

  `? : ((? -> ?) -> ?) -> ((? -> ?) -> ?)` with `?(?)(f) = f(?(f))`,

and then to prove that `fix : (? -> ?) -> ?` is the **least fixed point** of `?` -- the
true equation
`fix = fix(fun F fun f. f(F(f)))` (cf. the text following Exercise 4.9).

**Construction.** Writing `G = (? -> ?)` and `E = (G -> ?)`, the term `fun F fun f. f(F(f))`
is built from the
cartesian-closed combinators: `? = curry ?` where `? : E x G -> ?` is
`? = eval_{?,?} comp <?_G, eval_{G,?}>`, sending `<F, f>` to `f(F(f))`. Approximability is
automatic
(`bigPsi`); the defining equation `?(?)(f) = f(?(f))` is `bigPsi_apply` (Theorem 3.12's `curry`
b-rule
plus the `eval`/projection laws).

**`fix = fix(?)`. Representing `fix` as the element `toFilter (fixMap V)` in `|E|`:

* `bigPsi_fix` -- `?(fix) = fix`: indeed `?(fix)(f) = f(fix(f)) = f(fix f) = fix f = fix(f)`
since
`fix(f) = fix f` is a fixed point of `f` (Theorem 4.1);

```

```

* `bigPsi_least` -- if `?(?) sqsub ?` then `fix sqsub ?`: pointwise, `?(f) = f(?(f))`
  sqsub ?(f)` makes `?(f)`
  a pre-fixed point of `f`, so `fix f sqsub ?(f)` (Theorem 4.1's minimality), i.e. `fix(f)
  sqsub ?(f)`;
* `fix_eq_fixElement_bigPsi` -- combining the two, `fix = fix(?)` (= fixElement `?`, Theorem
  4.1's
  canonical least fixed point).

The operator data `bigPsi` is choice-free; equalities of elements/operators go through the
project's permitted `Element.ext` / `ext_of_toElementMap`.

# Exercise 4.10 (Scott 1981, PRG-19, Lecture IV) -- the relativized domain `D?`

Given a domain `?` and an element `a` in `|?|`, construct a domain `D?` whose elements are
  exactly
the elements below `a`:

  `|D?| = {x in |?| ? x sqsub a}`.

**Construction.** `relSystem a` keeps the same tokens and master `Delta`, but takes as
  neighbourhoods
  exactly the *members of the filter `a`* (`mem X := a.mem X`). This is a neighbourhood system
  because
  `a`, being a filter, contains `Delta` and is closed under consistent intersections. Its filters
  are in
  order-isomorphism with the elements of `?` below `a` (`relIso`): a `D?`-filter `g` is sent to
  its
  `?`-upward-closure `embed a g`, and an element `x sqsub a` is sent to its restriction `
  restrict a x`
  (automatically a `D?`-filter since `x.mem subseq a.mem`).

**Restriction of `f`.** If `f : ? -> ?` is approximable and `f(a) = a` (e.g. `a = fix(f)`, by
  Theorem 4.1), then `f` restricts to an approximable `f' : D? -> D?` (`relMap`) with the same
  action (`embed a (f'(g)) = f(embed a g)`, `relMap_toElementMap_embed`). The codomain condition
  `f.rel X Y ? a.mem Y` for `a`-neighbourhoods `X` holds because `X sqsub a`, so `Y in f(X)
  sqsub f(a) = a`.

```

```

**How many fixed points does `f` have? When `a = fix(f)`, *exactly one* (`
  relMap_unique_fixed`):
the top element of `D?` (corresponding to `fix(f)` itself). Any fixed point of `f` below `fix(f)
)` is
a pre-fixed point, hence `? fix(f)` by leastness (`fixElement_below_unique`), so it *equals* `
  fix(f)`.

All constructions are **choice-free**; equalities of `Element`/maps use the project's permitted
`Element.ext`.

# Exercise 4.11 (Scott 1981, PRG-19, Lecture IV) -- Plotkin's uniqueness of `fix`

(Suggested by G. Plotkin.) Regard `fix` as assigning a fixed-point operator `F_? : (? -> ?)
-> ?`
to each domain `?`. Scott asks to show `fix` is the unique such assignment `? ? F_?`
subject to:

* (i) `F_? : (? -> ?) -> ?`;
* (ii) `F_?(f) = f(F_?(f))` for all `f : ? -> ?` (each value is a fixed point);
* (iii) (uniformity) whenever `f_0 : ?_0 -> ?_0`, `f_1 : ?_1 -> ?_1` and `h : ?_0 -> ?_1` satisfy
    `h(False) = False` and `h comp f_0 = f_1 comp h`, then `h(F_{?_0}(f_0)) = F_{?_1}(f_1)`.

fix satisfies (iii) (fixElement_uniform): writing `fix(f_0) = sqsup _n f_0?(False)` (
    Theorem 4.2(iii)),
the intertwining `h comp f_0 = f_1 comp h` together with `h(False) = False` gives `h(f_0?(False)) = f_1?(False)` by induction,
and `h` preserves directed unions, so `h(fix f_0) = sqsup _n f_1?(False) = fix f_1`.

Uniqueness (fix_unique_of_uniform): given any `F` obeying (ii) and (iii), and any `f :
? -> ?`,
apply (iii) with the inclusion `h = ? : ?_{fix f} ?` of the relativized domain (Exercise
4.10).
`?(False) = False` (inclMap_bot) and `? comp f' = f comp ?` (inclMap_intertwine, from
relMap_toElementMap_embed). Hence `?(F_{?_{fix f}}(f')) = F_?(f)`. But `F_{?_{fix f}}(f')` is
a
fixed point of `f'` by (ii), and `f'` has exactly one fixed point (Exercise 4.10,
relMap_unique_fixed) -- the top point `fix f` -- so the left side is `?(fix f) = fix f`.
Therefore
`F_?(f) = fix f`.

```

```

`fix` satisfying (i)/(ii) is Theorem 4.2 (`fixMap`, `fixMap_fixed`). The uniqueness proof uses
  only
the project's permitted `Element.ext`; the inclusion data `inclMap` is choice-free.

# Exercise 4.12 (Scott 1981, PRG-19, Lecture IV)

*Need an approximable `f : ? -> ?` have a maximum fixed point? Give an example where
there are
many fixed points.*

**No.** The identity map `I_?` has every element as a fixed point. Taking `?` to be Scott's
Example 1.2 (the fork `T` with `False ? {0}-total`, `False ? {1}-total` and the two total
elements
incomparable), `I_T` has three fixed points `False`, `elemZero`, `elemOne`; the two total ones
are
maximal and incomparable, so there is no greatest fixed point (`no_greatest_fixedPoint`) --
in
particular no maximum. This is the simplest counterexample to "a least fixed point is a maximum
fixed point".

Uses `Classical.choice` only through Example 1.2's finite `fin_cases`/`simp` classification,
exactly
as that file does.

# Exercise 4.13 (Scott 1981, PRG-19, Lecture IV) -- eliminating the circularity

The proof of Theorem 4.1 uses the integers (the chain `f?(False)`), whereas the proof of
Theorem 4.6
uses 4.1 -- *a hint of circularity*. Scott shows it can be eliminated:

**(1)** If a domain `α` has an element `a` where, for `f : α → α`, the relation `f(a) ≤ a`
holds,
then the least fixed point can be defined *without* the integers, purely by a greatest-lower-
bound:

`fix(f) = ⨅ {x in |?| ? f(x) ≤ x}`,

and `fix(f) ≤ a`. Here `b = ⨅ {...}` is a well-defined element by Exercise 1.18 (`sInf`,
the
intersection of a non-empty family of filters). The argument uses only the monotonicity of
`f : |?| → |?|` -- no directed sups, no integers:

* `f(b) ≤ x` whenever `f(x) ≤ x` (since `b ≤ x` so `f(b) ≤ f(x) ≤ x`), hence `f(b) ≤ b`;
* then `f(f(b)) ≤ f(b)`, so `b ≤ f(b)` too; thus `b = f(b)`;
* `b` is least among pre-fixed points, in particular the least fixed point.

This is `monoFix` / `monoFix_isFixed` / `monoFix_least` / `monoFix_le_preFix` below. It is
entirely
**choice-free** (`#print axioms subseteq {propext, Quot.sound}`).

**(2)** The argument uses only monotonicity, and `(1)` always applies to power-set domains `P
A`
(take `a = A`, the top element, where `f(A) ≤ A` is automatic) -- see Exercise 4.14.

**(3)** With `(1)` one re-establishes the recursion principle behind 4.6 directly: for any
structured
set `(Z, z, *)` there is a unique `s : Nat → Z` with `s(0) = z` and `s(n+) = s(n)*`
(`exists_unique_nat_rec`). This is the choice-free primitive recursion theorem; combined with
`(1)`
it removes the circularity (one no longer needs 4.1 to build the iteration).

**(4)** Specializing `(3)` to `(Nat, 0, +)` recovers the very iteration `n ↦ f^n` used in
4.1
(`nat_iterate_unique`), closing the loop without circularity.

# Exercise 4.14 (Scott 1981, PRG-19, Lecture IV) -- ` $P A$ ` has a maximum fixed point

*Need a monotone function `f :  $P A \rightarrow P A$ ` always have a maximum fixed point?

**Yes.** Contrast this with Exercise 4.12, where a general domain ` $?^?$ ` admits monotone (indeed
approximable) maps `f :  $? \rightarrow ?$ ` with no greatest fixed point. The reason is that ` $P A$ ` -- the
power-set domain, whose elements are arbitrary subsets of ` $A$ ` ordered by inclusion -- is a
complete lattice: arbitrary unions and intersections exist. So both halves of the
Knaster-Tarski theorem apply.

```

```

* Greatest fixed point (this exercise): `gfpSet f = ? {x ? x subseq f(x)}` (the union
  of the
  *post*-fixed points) is a fixed point and dominates every fixed point (`gfpSet_isFixed`,
  `gfpSet_greatest`).
* Least fixed point (Exercise 4.13(2), the dual): `lfpSet f = ? {x ? f(x) subseq x}` (
  the
  intersection of the *pre*-fixed points) is a fixed point and is dominated by every fixed
  point
  (`lfpSet_isFixed`, `lfpSet_least`). This is exactly Scott's remark 4.13(2) that the
  intersection
  construction "can always be applied to power-set domains `P A`" -- here `a = A` is the
  automatic
  pre-fixed point `f(A) subseq A`.

```

Both constructions use **only monotonicity** and the complete-lattice structure of ``P A``; they are entirely **choice-free** (``#print axioms subseq {propeq, Quot.sound}``).

# Exercise 4.15 (Scott 1981, PRG-19, Lecture IV) -- a maximal (and a least) fixed point

(For set theorists.) Let `f : |?| -> |?|` be a monotone function on the elements of a
domain. Then
`f` has a maximal fixed point -- a fixed point that cannot be extended to a larger one --
and
(consequently) a least fixed point.

**Maximal fixed point (Zorn).** Consider the set `S = {x ? x sqsub f(x)}` of post-fixed
points. It is
non-empty (`False` in `S`) and every chain `C` subseq `S` has an upper bound in `S`: its
union `sqsup C`
(Exercise 1.24's `chainUnion`, Scott's "use 2.11 to remark `sqsup C` in `|?|`") is again post-
fixed, since
each `x` in `C` has `x sqsub f(x) sqsub f(sqsup C)`. By Zorn's Lemma (`zorn_le_0`) `S` has
a maximal element `m`.
Then `m` is a fixed point: `m sqsub f(m)` (it is in `S`) and `f(m) sqsub m` (because `f(m)`
in `S` too, by
monotonicity, and `m` is maximal). It is maximal among fixed points
(`exists_maximal_fixedPoint`).

```

```

**Least fixed point.** Having produced some fixed point `m`, we have `f(m) sqsub m`, so
Exercise
4.13(1) (the monotone-only intersection construction `monoFix`) applies and yields the least
fixed
point `fix(f) = {x ? f(x) sqsub x} sqsub m` (`exists_least_fixedPoint`).

This is the explicitly classical exercise (Zorn ? `Classical.choice`), exactly like
Exercise
1.24; the `chainUnion` construction itself is choice-free.

# Exercise 4.16 (Scott 1981, PRG-19, Lecture IV) -- the optimal fixed point

(For fixed-point nuts.) Scott's step (1): for any non-empty set `S` of fixed points of a
monotone
`f :  $\alpha \rightarrow \alpha$ , the greatest lower bound ` $\text{f\_sInf\_le}$ ` (Exercise 1.18 ` $\text{sInf}$ `) satisfies

`f(?S) sqsub ?S` ( $\text{f\_sInf\_le}$ )

-- indeed ` $\text{f}(?S) \text{sqsub } f(s) = s$  for each `s` in `S`, so ` $\text{f}(?S)$  is a lower bound of `S`.
Being a pre-fixed
point, ` $?S$  carries (Exercise 4.13(1)'s ` $\text{monoFix}$ `) the least fixed point ` $\text{optimalFix } S$  with

`optimalFix S sqsub ?S sqsub s` for every `s` in `S` ( $\text{optimalFix\_le}$ ),

so ` $\text{optimalFix } S$  is a fixed point lying below every member of `S`, and it is consistent
with
each `s` in `S` (their common upper bound is `s` itself, ` $\text{optimalFix\_consistent}$ `). Taking `S`
to be the
set of maximal fixed points (which exist by Exercise 4.15) gives the fixed point that is
below all
the maximal ones, consistent with all other fixed points -- Scott's "optimal" fixed point.

The data ( $\text{optimalFix}$ ) is choice-free; only the appeal to Exercise 4.15 for the supply
of
maximal fixed points is classical.

# Exercise 4.17 (Scott 1981, PRG-19, Lecture IV) -- least solution in a monoid power-set

(For algebraists.) Let  $\langle S, 1, * \rangle$  be a monoid (a semi-group with unit). Then  $\mathcal{P} S$  is a domain
-- in
fact a complete lattice (Exercise 4.14). For  $a, b \in S$ , what is the least  $x \in \mathcal{P} S$ 
with

 $x = \{1\} \cup \{a, b\} \cup x * x$ , where  $x * y = \{t * u \mid t \in x, u \in y\}$ ?

Answer. The least solution is the submonoid generated by  $\{a, b\}$  -- i.e. the set of
all
finite products of  $a$ 's and  $b$ 's (including the empty product  $1$ ):

 $\text{lfpSet } (F \ a \ b) = \langle \{a, b\} \rangle \ (= \text{Submonoid.closure } \{a, b\})$ .

The operator  $F \ a \ b \ x = \{1\} \cup \{a, b\} \cup x * x$  is monotone (pointwise  $*$  is monotone), so
by
Exercise 4.14 (the dual Knaster-Tarski over the complete lattice  $\mathcal{P} S$ ) its least fixed point
 $\text{lfpSet } (F \ a \ b)$  exists; we identify it with the submonoid closure ( $\text{lfpSet\_eq\_closure}$ ): a
fixed
point of  $F$  is exactly a submonoid containing  $\{a, b\}$ , and the least such is the closure.

Need the fixed point be unique? No. In any monoid the whole set  $\text{Set.univ}$  is also a
fixed
point ( $F \ a \ b \ \text{univ} = \text{univ}$ , since  $s = 1 * s \in \text{univ} * \text{univ}$ ). So whenever the monoid is not
generated by  $\{a, b\}$  there are at least two fixed points: taking  $S = \text{Nat}$  (under  $*$ ) and  $a = b = 1$ ,
the least solution is  $\{1\}$  while  $\text{Set.univ}$  is another ( $\text{fixedPoint\_not\_unique}$ ).

The constructions are choice-free ( $\# \text{print axioms subseteq } \{\text{propeq}, \text{Quot.sound}\}$ ),
inheriting
 $\text{lfpSet}$  from Exercise 4.14.

# Exercise 4.18 (Scott 1981, PRG-19, Lecture IV)

*In Example 4.3 there are many unproved assertions about `N` and `F`. These should be checked.*

`Example43.lean` builds the natural-number domain `N`, the total elements `n = natElem n`, and
the
structure maps `succ`, `pred`, `zero` with their value equations. This file discharges the
remaining
*structural* assertions Scott leaves implicit:

* Element classification (`element_classification`): `|N|` consists of exactly `False` and
the total
elements `n` -- `N` is genuinely the flat domain over `Nat`. (This is the assertion that
makes `N`
"THE domain of integers".)
* Peano's axioms for the total elements ` $\{n\}, 0, \text{succ}$ `:
- `natElem_injective` / `succMap_injective`: distinct numerals are distinct elements, and `
succ` is
one-one;
- `natElem_zero_ne_succ` / `zero_ne_succMap`: `0` is not a successor;
- `predMap_succMap_natElem` (already in `Example43`): `pred comp succ = id` on numerals.

The classification is classical (it decides whether `x` contains a singleton, exactly as
Example 4.3's
`zeroMap` is classical); the injectivity / zero-is-not-a-successor facts are choice-free.

# Exercise 4.19 (Scott 1981, PRG-19, Lecture IV) -- verifying Example 4.4

Example 4.4 leaves many assertions to the reader. This module discharges the two explicitly
requested ones:

* "Peano's Axioms" for  $\{0,1\}^*$ . ** The structured set  $\langle \text{Sigma}^*, ?, 0^*, 1^* \rangle$  (here  $\text{Sigma}^* = \text{List Bool}$ ,
 $? = []$ , and the two successors  $b \mapsto b :: *$ ) satisfies the natural two-successor
analogue of
Definition 4.5:  $?^*$  is not a successor ( $\text{peano\_nil\_ne\_cons}$ ), each successor is injective
( $\text{peano\_cons\_injective}$ ), the two successor ranges are disjoint ( $\text{peano\_cons\_disjoint}$ ), and
the
*induction* principle holds ( $\text{peano\_induction}$ ). So  $\text{Sigma}^*$  is the free monoid on two
generators --
the binary-tree analogue of  $\langle \text{Nat}, 0, ^{+} \rangle$ .

* one :  $C \rightarrow T$  is definable from the rest of the structure by a fixed-point equation. **
We first
build the three tests  $\text{empty}, \text{zero}, \text{one} : C \rightarrow T$  as honest approximable maps (Scott: "it
is an
exercise to show these are approximable"), via a uniform head-test combinator  $\text{liftC}$ . We
then
show

```

```

`one(x) = cond(empty(x), false, cond(zero(x), false, true))`

on every generator of `|C|` (`one_def_strElem`, `one_def_strBot`), exhibiting `one` as the
solution of a fixed-point/recursion equation in the remaining structure `` (the right-hand side does not mention `one`, so this is the trivial fixed point
--
Scott's point that the tests are not independent).

The `liftC` combinator (a map `C -> V` determined by its values on the partial elements `
sigmaFalse` and the
total elements `sigma`, subject to two monotonicity conditions) is reusable; with it one
likewise gets
Scott's `tail : C -> C` (`tail(bx) = x`, `tail(?) = False`), here noted but not needed for `
one`.

The `liftC` *data* is **choice-free**; the truth-domain tests inherit `Classical.choice`
structurally from `T` (Example 1.2), exactly as `Example23.parityMap` and `Example43.zeroMap`
do.

# Exercise 4.20 (Scott 1981, PRG-19, Lecture IV)

For approximable `f, g : ? -> ?` prove that

`fix(f comp g) = f(fix(g comp f))`.

In this development `f comp g` is `f.comp g`, whose elementwise action is
`f.toElementMap comp g.toElementMap` (`toElementMap_comp`). The least fixed point of an
endomap is
`fixElement` (Theorem 4.1), with its fixed-point equation `toElementMap_fixElement` and its
least-pre-fixed-point characterization `fixElement_le_of_toElementMap_le`.

The proof is the classical "rolling rule" / dinaturality of the fixed-point operator:
`f(fix(g comp f))` is a fixed point of `f comp g`, hence `?` the least one, and a symmetric
argument
gives the reverse inclusion. Everything stays at the level of `V.Element`, so the whole file is
**choice-free** (`#print axioms subseteq {proptext, Quot.sound}`).

# Exercise 4.21 (Scott 1981, PRG-19, Lecture IV) -- `<= ` as a unique fixed point; addition &
multiplication

Scott asks to show that the less-than-or-equal-to relation `? subseq Nat x Nat` is *
uniquely* determined
by the fixed-point equation

`? = {(n, n) ? n in Nat} U {(n, m+) ? (n, m) in ?}`.

Working in the power-set domain `P(Nat x Nat)` (a complete lattice, Exercise 4.14), the right
-hand side
is a monotone operator `leOp`. We show:

* `leRel = {(n, m) ? n <= m}` solves the equation (`leRel_isFixed`);
* the solution is unique (`leOp_unique`): for any fixed point `u` one proves, by
induction on
the second coordinate, that `(n, m) in u <-> n <= m`. (Unlike a general least-fixed-
point situation,

```

```

    here the equation pins the relation down completely, because the clause `(n, m^+)` never
    produces a
    pair with second coordinate `0`.)

Scott then considers `

` with `x^+ = {n^+ ? n in x}` and the **unique function
**
`[*] : Nat -> P Nat` of 4.13(3) determined by `[0] = Nat` and `[m^+] = [m]^+`. We identify it
as the up-set
`[m] = {k ? m <= k}` (`upSet`), with `upSet_zero`/`upSet_succ` the two recursion equations
and
`upSet_unique` their uniqueness (4.13(3)).

The structures `` and `<[m], m, ^+>` are **uniquely isomorphic** via `n |-> m + n`
(`addIso`), connecting the isomorphism with **ordinary addition** (`addIso_apply`): the unique
structure-preserving bijection sends `n` to `m + n`.

Finally, **multiplication**: the hint equation `n*Nat = {0} U {n + m ? m in n*Nat}` has, as
its least
solution in `P Nat`, exactly the set of multiples of `n` (`mulOp_lfp_eq_multiples`).

All set-level constructions are **choice-free** (`#print axioms subseq {propeq, Quot.sound
}`).

# Exercise 4.22 (Scott 1981, PRG-19, Lecture IV) -- carving a Peano model out of a partial one

Suppose  $N^*$  is a structured set  $\langle N^*, 0, ^+\rangle$  satisfying only axioms (i) and (ii) of
Definition 4.5 -- i.e.  $0 \neq n^+$  (zero is not a successor) and  $^+$  is injective -- but not
necessarily*
the induction axiom (iii). Must there be a subset  $N \subseteq N^*$  that satisfies (i), (ii),
and (iii)?**

**Yes.** Following Scott's hint, take the least fixed point in  $P(N^*)$  (Exercise 4.14 /
4.13(2),
the dual Knaster-Tarski over the complete lattice  $P(N^*)$ ) of the monotone operator

$$g(x) = \{0\} \cup x^+ = \{0\} \cup \{n^+ \mid n \in x\}.$$

This least fixed point nats is the smallest subset of  $N^*$  containing  $0$  and closed under
 $^+$ 
(zero_mem_nats, succ_mem_nats). On the subtype  $N = \{m \mid m \in \text{nats}\}$ :

* (i)  $0 \neq n^+$  and (ii)  $^+$  injective are inherited from  $N^*$ ;
* (iii) induction holds by minimality of the least fixed point: a subset of  $N$  closed
under
 $0/^+$  pulls back to a pre-fixed point of  $g$  in  $P(N^*)$ , which therefore contains nats.

So  $\langle N, 0, ^+\rangle$  is a genuine model of Peano's Axioms (peanoSub), giving
exists_peano_submodel.

(For set theorists.)* The existence of such an  $N^*$  at all is guaranteed by the axiom of
infinity: the standard  $\langle \text{Nat}, 0, ^+\rangle$  is one (PeanoModel Nat, recorded as natPeano), and
indeed it
already satisfies (iii), so it is its own carved-out model.

The subset nats is built choice-free (lfpSet); the PeanoModel packaging of peanoSub and
the
existence statement live over Classical.choice exactly as Theorem 4.6's bijection does.

# Exercise 4.23 (Scott 1981, PRG-19, Lecture IV) -- Eilenberg's uniqueness criterion

(Suggested by S. Eilenberg.) Let `f : ? -> ?` be approximable, and let `a_n : ? -> ?` be a
sequence of
approximable maps with

* (i) `a_0(x) = False` for all `x`;

```

```

* (ii) `a_n sqsub a_{n+1}` in `? -> ?`;
* (iii) `sqsup_n a_n = I_?` (the identity);
* (iv) `a_{n+1} comp f = a_{n+1} comp f comp a_n`.

**Then `f` has a unique fixed point** (`f_unique_fixedPoint`).

Existence is the Fixed-point Theorem 4.1 (`fix f = sqsup_n f?(False)`). For uniqueness,
  suppose `x = f(x)`.
Following Scott's hint, one shows by induction on `n` that

  `a_n(x) sqsub a_n(fix f)`                (`approx_le`),

the step using (iv) twice and `x = f(x)`, `fix = f(fix)`:
`a_{n+1}(x) = a_{n+1}(f(x)) = a_{n+1}(f(a_n(x))) sqsub a_{n+1}(f(a_n(fix))) = a_{n+1}(f(fix))`
  `= a_{n+1}(fix)`.
Then, since `sqsup_n a_n = I` evaluates pointwise to `x = sqsup_n a_n(x)` and `a_n(x) sqsub a_n(fix) sqsub fix`, the least
upper bound `x` lies below `fix`; together with `fix sqsub x` (minimality of the least fixed
point) this
forces `x = fix`. Hence the fixed point is unique.

We phrase conditions (ii)+(iii) together in the pointwise form `IsLUB {a_n(x)} x` (equivalent
to
`sqsup_n a_n = I` via the pointwise suprema of the function space `? -> ?`, Theorem 3.10):
that `x` is the
*least upper bound* of the family `{a_n(x)}` already records both that the family is bounded by
`x`
(absorbing (ii)'s monotonicity into the LUB) and that nothing smaller bounds it. The argument
uses
only the project's permitted element-extensionality through `Theorem41`.

# Exercise 4.24 (Scott 1981, PRG-19, Lecture IV) -- Schroder-Bernstein via a fixed point

(For set theorists.) Let `f : A -> B` and `g : B -> A` be one-one (injective, not
necessarily onto).
**Then there is a one-one correspondence `h : A ? B`** (`schroeder_bernstein`).

Following Tarski's hint, work in the power-set domain `P A` (a complete lattice) and take a
fixed
point `X` of the monotone operator

`T(X) = (A ? g(B)) U g(f(X))`,

which exists by Knaster-Tarski (Exercise 4.14 / 4.13(2), here `lfpSet`). With `X = T(X)` fixed,
define

`h(a) = f(a)` if `a in X`,
`h(a) = g^-1(a)` if `a notin X`

-- well-defined because `a notin X = T(X)` forces `a in g(B)` (it is not in `(A ? g(B))`),
so `a` has a
unique `g`-preimage (`mem_range_of_not_mem`). The map `h` is:

```

```

* **injective** (`sbFun_injective`): within `X`, by injectivity of `f`; outside `X`, by
  injectivity
  of `g`; the mixed case is impossible -- `f(a_1) = g^-1(a_2)` would put `a_2 = g(f(a_1))` in
  `g(f(X))` subseteq `X`;
* **surjective** (`sbFun_surjective`): for `b` in `B`, if `g(b) notin X` then `h(g(b)) = b`;
  if `g(b) in X`
  then `g(b) in g(f(X))`, so `g(b) = g(f(a))` with `a` in `X`, whence `b = f(a) = h(a)`.

Packaged as the equivalence `schroeder_bernstein_equiv`. This is a *set theorists'* exercise
and is
inherently classical; the construction of `h` uses `Classical.choice` (the `g`-preimage),
exactly as
the statement demands.

# Exercise 4.25 (Scott 1981, PRG-19, Lecture IV) -- the unary sequence domain `C_1`

```

"Perhaps the domains N and C are not exactly analogous?" C (Example 4.4) was built over the two-letter alphabet $\{0,1\}$. Scott asks to build the analogue C_1 over $\{1\}^*$ -- finite strings of 1's, which we encode by their length n in Nat (so $1? \leftrightarrow n$). The neighbourhoods are the **tails** and the **singletons**:

$$C_1 = \{ \{1? \ ? \ m \ \geq \ n\} \ ? \ n \ \text{in } Nat \} \cup \{ \{1?\} \ ? \ n \ \text{in } Nat \} \quad (\text{tail } n = \{m \ ? \ n \ \leq \ m\}, \{n\}).$$

This is again a nested-or-disjoint system (`ofNestedOrDisjoint`): the tails form a descending chain and a singleton is either inside a tail or disjoint from it. The total elements are the finite strings $1?$ (`oneElem n = {n}`) and the partial elements $1?False$ ("at least n ones", `oneBot n = (tail n)`).

The structure **analogous to C** is the single successor $x \mapsto 1x$ (`consMap`, prepending a 1, i.e. shifting the length up by one), with `consMap_oneElem`/`consMap_oneBot`. Crucially -- and this is Scott's point that N and C are **not** analogous -- C_1 is **not flat** like N : the successor has a genuine **infinite** fixed point $1^\infty = 1*1^\infty$ (`infElt`, `infElt_eq`), the limit `sqsup_n 1?False` of the tails, which has no counterpart among the elements `False, 0, 1, 2, ...` of the flat domain N . So C_1 is the genuine unary analogue of C (`= C_2`), distinct from N .

Finally, the systems are **related by approximable maps**: e.g. `relateNToC1 : N -> C_1` sends the numeral n to the finite string $1?$ and is strict (`False -> False`) -- the natural "length $\mapsto$ unary expansion" map (`relateNToC1_natElem`, `relateNToC1_bot`).

The data (`C_1`, `consMap`, `relateNToC1`) is **choice-free** (`#print axioms subseq {proptext, Quot.sound}`).

# Lecture V (S5) -- Table 5.5: a table of combinators

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981),
    Lecture V,
*Typed fun -calculus*. Table 5.5 summarizes how the standard combinators are defined by `fun` -
    notation.
In the neighbourhood-system/approximable-map framework of these lectures, each combinator
    scheme is

```

realized as a concrete **approximable map**, and Scott's ``fun``-equations become the **value equations** of those maps (proved through the projection/pairing/``eval``/``curry``/``fix`` API of Lecture III-IV).

```
| Scott's table | here | value equation |
| ----- | ---- | ----- |
| `P_0 = fun x,y.x` | `P_0 = proj_0` | `P_0<x,y> = x` |
| `P_1 = fun x,y.y` | `P_1 = proj_1` | `P_1<x,y> = y` |
| `pair = fun x fun y.<x,y>` | `pairC = curry I` | `pairC x y = <x,y>` |
| `diag = fun x.<x,x>` | `diag = <I,I>` | `diag x = <x,x>` |
| `funpair = fun f fun g fun x.<f x, g x>` | `funpairC` | `funpairC f g x = <f x, g x>` |
| `proj_i`n | base cases `P_0,P_1` | (scheme; see note) |
| `inv_{i,j}`n | base case `swapC` | `swapC<x,y> = <y,x>` |
| `eval = fun f,x.f x` | `evalC = evalMap` | `evalC<f,x> = f x` |
| `curry = fun g fun x fun y.g(x,y)` | `curryC = ofIso` | `curryC g x y = g<x,y>` |
| `comp = fun g,f fun x.g(f x)` | `compC = curry ...` | `compC<g,f> = g ∘ comp f` |
| `const = fun k fun x.k` | `constC = curry proj_0` | `constC k x = k` |
| `fix = fun f !x.f x` | `fixC = fixMap` | `fixC f = fix f` |
```

A note on ⁿ-ary schemes. Scott stresses that the table entries are **schemes**: ⁿ-tuple, ``proj_i`n`, ``inv_{i,j}`n` are families parameterized by an arity ⁿ. The framework models the ⁿ-fold product by **iterating** the binary product ``prod``, so the ⁿ-ary combinators are obtained

by iterating the binary ones recorded here (``P_0``/``P_1`` are ``proj_0`2`/``proj_1`2`; ``pairC`` is the ``2``-tuple; ``swapC`` is ``inv_{0,1}`2`). We give the binary base cases as concrete maps.

All combinators are **data**; the genuinely first-order ones (``P_0``, ``P_1``, ``pairC``, ``diag``, ``funpairC``, ``swapC``, ``evalC``, ``constC``, ``compC``) are **choice-free** (``#print axioms subseq {propext, Quot.sound}``). ``curryC`` and ``fixC`` are built from the established ``ofIso``/``fixMap`` API.

# Lecture V (S5) -- Theorem 5.1 (Scott 1981, PRG-19)

**Theorem 5.1.** Every typed `fun`-term `tau` defines an approximable function of its free
variables.

Scott proves this by induction on the (limited) syntax of `fun`-terms. There are exactly five
cases,
and in the neighbourhood-system framework each is realized by a construction already shown to
be
approximable in Lectures II-III. The interpretation `?tau?` of a term with free variables of
types
`?_0, ..., ?_n?_1` (collected into the context product `Gamma = ?_0 x ? x ?_n?_1`) is an *
approximable map*
`Gamma -> ?`, built as follows:

| term `tau` | interpretation | approximable by |
| ----- | ----- | ----- |
| a variable `x_i` | a projection `Gamma -> ?_i` | Def 3.3 (`proj_0`/`proj_1`) |
| a constant `k` | `constMap` | Lemma 3.6 |
| a tuple `<sigma_0, sigma_1>` | `<?sigma_0?, ?sigma_1?> = paired` | Prop 3.4 |
| an application `sigma_0(sigma_1)` | `eval comp <?sigma_0?, ?sigma_1?>` | Thm 3.11 + Thm 2.5
|
| an abstraction `fun x.sigma` | `curry ?sigma?` | Thm 3.12 |

Because every one of these lands in `ApproximableMap`, "defines an approximable function" holds
*by
construction* -- the content of Theorem 5.1 is that these five closure operations exist and
compute
the intended values, which is what we record here (the value equations `*_apply`). The
genuinely
recursive cases (tuple, application, abstraction) carry the induction hypothesis that the
subterms `sigma_i` are already approximable.

```

```

This module collects the five closure facts as concrete lemmas; everything is choice-free.

# Lecture V (S5) -- Theorem 5.2 (Scott 1981, PRG-19)

**Theorem 5.2.** For suitably typed `fun`-terms the following equation is true:

`(fun x_0, ..., x_n?_1. tau)(sigma_0, ..., sigma_n?_1) = tau[sigma_0/x_0, ..., sigma_n?_1/x_n?_1].`

This is the fundamental conversion (b-substitution) rule. Scott proves it by induction on `tau`,
reducing to the one-variable case and using three "true equations" along the way. In the
neighbourhood-system framework, where a term-in-context is an approximable map, the one-
variable
rule is exactly the computation law of `curry`/`eval` from Theorem 3.12, and the inductive
helper
equations are the corresponding combinator identities:

* b (one variable, in context).** With `?tau? = g : Gamma x ?? -> ?'`, the term `fun x.
tau` is `curry g` and
applying it to a constant `sigma` substitutes `sigma` for `x`:
`eval comp <curry g, const sigma> = g comp <I, const sigma>` (`beta`).
* tuple.** `(fun x.<tau_0, tau_1>)(sigma) = <(fun x.tau_0)(sigma), (fun x.tau_1)(sigma)>`
(`beta_tuple`).
* abstraction (Scott's `inv` step).** `(fun x.fun y.tau)(sigma)(y) = tau[sigma/x]` evaluated,
i.e. the double-curry
application law (`beta_abs`).

The base value law `(fun x.tau)(sigma) = tau[sigma/x]` evaluated pointwise is `
toElementMap_curry_apply`.
Everything here is at the level of approximable maps; the map equation `beta` uses the
permitted
`ext_of_toElementMap`, the value equations are choice-free.

/-!
# Lecture V (S5) -- Proposition 5.3 (Scott 1981, PRG-19)

The least fixed point of  $\lambda x, y. \langle \tau(x, y), \sigma(x, y) \rangle$  is the pair with coordinates
 $\lambda x. \tau(x, \lambda y. \sigma(x, y))$  and  $\lambda y. \sigma(\lambda x. \tau(x, y), y)$ .

This is Bekic's theorem: the least solution of the simultaneous system  $x = \tau(x, y)$ ,
 $y = \sigma(x, y)$  is computed coordinatewise by nested least fixed points.

In this framework  $\tau : ?_0 \times ?_1 \rightarrow ?_0$  and  $\sigma : ?_0 \times ?_1 \rightarrow ?_1$  are
approximable, and the pair-valued
map is  $F = \langle \tau, \sigma \rangle = \text{paired } \tau \text{ } \sigma : ?_0 \times ?_1 \rightarrow ?_0 \times ?_1$  whose least fixed
point  $F.\text{fixElement}$  (Thm 4.1)
is the least solution Scott invokes in his hint. We build:

*  $\text{secFixX } \tau : ?_1 \rightarrow ?_0$ , the approximable map  $y \mapsto \lambda x. \tau(x, y)$  ( $\text{fix comp curry}$ 
  ( $\tau \text{ comp swap}$ ));
*  $\text{outerOp } \tau \text{ } \sigma : ?_1 \rightarrow ?_1$ , the approximable map  $y \mapsto \sigma(\lambda x. \tau(x, y), y)$ ;
*  $\text{ystar} = (\text{outerOp } \tau \text{ } \sigma).\text{fixElement} = \lambda y. \sigma(\lambda x. \tau(x, y), y)$  and
   $\text{xstar} = \text{secFixX } \tau (\text{ystar}) = \lambda x. \tau(x, \text{ystar})$ .

The theorem  $\text{fixElement\_paired\_eq}$  states  $F.\text{fixElement} = \langle \text{xstar}, \text{ystar} \rangle$ , proved exactly as
Scott:
 $\langle \text{xstar}, \text{ystar} \rangle$  is a fixed-point pair (so  $F.\text{fixElement} \sqsubseteq \langle \text{xstar}, \text{ystar} \rangle$ ), and from the
least
solution  $\langle a, b \rangle$  one derives  $\lambda x. \tau(x, b) \sqsubseteq a$ , hence  $\text{outerOp}(b) \sqsubseteq b$ , hence
 $\text{ystar} \sqsubseteq b$ , hence
 $\text{xstar} \sqsubseteq a$ . All data is choice-free; the proof uses only the order on  $|?_i|$  and
the
universal properties of  $\text{fixElement}$ .

# Lecture V (S5) -- Proposition 5.4 (Scott 1981, PRG-19)

Let `x`, `y`, and `tau(x, y)` have the same type `?`, and let `g` range over `(? -> ?)`. Then
the
equation

```

```
`fun x. !y. tau(x, y) = !g. fun x. tau(x, g(x))`
```

is true.

In this framework ``tau : ? x ? -> ?`` is an approximable map. We model the two sides directly:

```
* the left side `fun x. !y. tau(x, y)` is `pfix tau := fix comp curry(tau)`, the
  approximable map sending
  `x` to the least fixed point of the section `y |-> tau(x, y)` (this is `!y.tau(x,y)`,
  manifestly
  approximable by Theorem 4.2 -- exactly Scott's appeal to 5.1 that "`f` is a function");
* the right side `!g. fun x. tau(x, g(x))` is the least fixed point `(recOp tau).fixElement`
  of the
  approximable operator `recOp tau := curry(tau comp <p_1, eval>)` on the function space,
  which sends a
  map `g` to `fun x. tau(x, g(x))`.
```

The proof is Scott's: ``pfix tau`` is a fixed point of ``recOp tau`` (so ``!g.... sqsub pfix tau``), and conversely the value ``(recOp tau).fixElement (x)`` is a fixed point of the section ``y |-> tau(x, y)`` (so ``pfix tau (x) sqsub (recOp tau).fixElement (x)`` for every ``x``). Everything is at the level of ``|?|`` and the function space, so the *data* (``pfix``, ``recOp``) is **choice-free** (``#print axioms subseq {propeft, Quot.sound}``); the final map equality goes through the permitted ``ext_of_toElementMap``.

# Theorem 5.6 (Scott 1981, PRG-19, S5) -- recursive functions are fun -definable

Scott's Theorem 5.6: every partial recursive  $h : \mathbb{N} \rightarrow \mathbb{N}$  is denoted by a fun -term whose
only constants
are `cond`, `succ`, `pred`, `zero`, `0`. The proof is by the standard generation of the partial
recursive functions: strict *starting* functions, closure under (multivariate) *composition*,
*primitive recursion*, and the *?-scheme* (least-number operator). We formalise the
constructive
heart of the proof -- the actual combinators Scott writes down -- over the natural-number
domain  $\mathbb{N}$ 
(Example 4.3) and the conditional `cond` (Exercise 3.26), proving the defining equations of
each
scheme. (We do not also wire these together against an external inductive predicate of partial
recursive functions; that closure is a routine but lengthy induction over the generation
grammar,
built entirely from the pieces below.)

## What is proved

* Strict starting functions (Scott's "simple device" `fun x. cond(zero(x), x, x)`):
- `strictId` with `strictId_natElem` (`= n`) and `strictId_bot` (`= False`);
- `strictProj_0 : N x N -> N`, the strict first projection, with `strictProj_0_natElem`,
`strictProj_0_bot_left`, `strictProj_0_bot_right` (strict in *both* arguments).

* Primitive recursion `primRec f g`, the least fixed point
`!k fun x,y. cond(zero(x), f(y), g(pred(x), y, k(pred(x), y)))`, with the scheme equations
- `primRec_zero` : `h(0, m) = f(m)`,
- `primRec_succ` : `h((n+1)^, m) = g(n, m, h(n, m))`,
- `primRec_bot` : `h(False, m) = False` (strict in the recursion argument).

* The ?-scheme `muRec f` / `muMap f`, the least fixed point
`!g fun x,y. cond(zero(f(x,y)), x, g(succ(x), y))` and `h = fun y. g(0, y)`, with

```

```

- `muRec_found` : `f(n, m) = 0 ? g(n, m) = n`,
- `muRec_step`  : `f(n, m) = (j+1)^ ? g(n, m) = g((n+1)^, m)`,
- `muRec_bot`   : `f(n, m) = False ? g(n, m) = False`,
and the capstone `muMap_eq_least`: if `n_0` is the least zero of `f(*, m)` (all earlier
values
positive totals), then `?(m) = n_0`.

All `cond`-based maps inherit `Classical.choice` structurally from the truth domain `T`
(Example 1.2) exactly as `cond`/`zeroMap` already do; the fixed points come from Theorem 4.1.

# Theorem 5.6 (Scott 1981, PRG-19, S5) -- the FULL closure: partial recursive ? fun -definable

`Theorem56.lean` builds the constructive heart (strict starting functions, the primitive-
  recursion
and ? combinators with their scheme equations). This file wires those pieces together against
Mathlib's **arity-aware** inductive predicates `Nat.Primrec`/`Nat.Partrec` (over `List.Vector
  Nat n`),
whose constructors are exactly Scott's generation grammar:

* `Nat.Primrec`: `zero`, `succ`, `get i` (projection), `comp`, `prec` (primitive recursion);
* `Nat.Partrec`: `prim`, `comp`, `rfind` (minimization).

We prove: every `Nat.Primrec`/`Nat.Partrec` function is denoted by an approximable map
`phi : ? -> N`, where `? := N^inf` (Exercise 3.16) is the **universal argument domain** --
  a `k`-ary
function is realised by a single map that depends only on coordinates `0..k-1`. The realisation
  is
*very strict* (Scott): `False` in any relevant coordinate forces `False`, which is what makes
  composition and
minimisation compose. The capstone is `partrec_lamDef` and the 1-ary corollary `partrec_one`.

/#!/ ### Minimisation (`rfind`).

The ?-operator searches *upward* for the least `k` with `f(k ::? v) = 0`. We carry the counter
in the
head coordinate of the stack. The search body over `prod (funSpace ? N) ?` is

`S(k, z) = cond(zero(f z), head z, k(push(succ(head z), tail z)))` :

if the current value `f z` is `0`, return the counter `head z`; otherwise recurse with the
counter
bumped by one. `searchMap` is the least fixed point, and `findMap` kicks the search off at
counter `0`.
The hard direction is **divergence**: when no `k` zeroes `f`, every finite approximant `S?(
False)` returns
`False` along the search trace, so the directed sup (Theorem 4.2(iii)) is `False` too. -/

# Exercise 5.7 (Scott 1981, PRG-19, S5) -- multi-variable `fun` and application from one-
variable forms

Scott asks for definitions of the two-variable abstraction and application

'''
fun x, y. tau          and          sigma(x, y)
'''

that use only the one-variable binder `fun v` and applications to one argument at a time,
with the
combinators `p_0`, `p_1`, `pair` doing the bookkeeping. He then asks to generalise to many
variables.

In the neighbourhood-system framework this is exactly the curry/uncurry isomorphism of
Theorem 3.12 together with surjective pairing:

* a two-variable function `sigma : D_0 x D_1 -> D_2` is applied "one argument at a time"
  through its curried
  form, `sigma(x, y) = (curry sigma)(x)(y)`; conversely `uncurry h` turns one-argument-at-a-
  time application
  back into a single application to a `pair`, and is literally built from one-argument pieces
  :
  `uncurry h = eval comp <h comp p_0, p_1>` (`uncurry_eq`), using only `eval`, `p_0`, `p_1`
  `, `pair`;
* the two-variable abstraction `fun x, y. tau` is `curry`, characterised by `(curry g)(x)(y) =
  g<x, y>`,
  i.e. it binds one variable and returns a one-variable function;
* the projections and pairing are tied together by surjective pairing `three-variable
generalisation

```

via nested currying $D_0 \times (D_1 \times D_2) \rightarrow D_3$, illustrating the pattern for arbitrarily many variables.

No new axioms are introduced beyond the project's `Element.ext` / `ext_of_toElementMap` machinery already used by `curry`/`uncurry`.

# Exercise 5.8 (Scott 1981, PRG-19, S5) -- combinatory completeness

> *(For combinator nuts.)* Table 5.5 was meant to show how combinators could be defined in
    terms
> of `fun`-expressions. Can the tables be turned to show that with enough combinators
    available, every
> `fun`-expression can be defined by combining combinators, using `sigma(tau)` as the *only*
    mode of
> combination?

The answer is *yes*: this is the classical theorem of *combinatory completeness* (bracket
abstraction). With the three combinators

...
I = fun x.x,          K = fun x,y.x,          S = fun f,g,x. f(x)(g(x))
...

available, every `fun`-abstraction can be eliminated in favour of pure application of
combinators. We
formalise this in the neighbourhood-system framework as follows.

* `Dom` packages a token type with its neighbourhood system, and `Dom.arrow A B` is the
    function
    domain `(A -> B)` (its carrier is `ApproximableMap A.sys B.sys`).

```

```

* `I`, `K`, `S` are realised as concrete elements (`Ielem`, `Kelem`, `Selem`) of the
  appropriate
  function domains, with their value equations `Ielem_apply`, `Kelem_apply`, `Selem_apply`
  proved through the project's `curry`/`eval`/projection API.
* `Poly X A` is the intrinsically-typed syntax of `fun`-bodies with one free variable of
  type `X`:
  the variable itself, closed constants (any element -- "enough combinators available"), and
  application. Its denotation `Poly.denote t : |X| -> |A|` is the open term as a function of
  the
  variable, i.e. the body whose abstraction `fun x.t` we wish to express.
* `CL A` is the syntax of variable-free combinator expressions: constants and application
  only
  (`sigma(tau)` is the only mode of combination). Its denotation `CL.denote : |A|` is a
  single element.
* `bracket : Poly X A -> CL (X.arrow A)` is bracket abstraction: it turns an open body `t`
  into a
  closed combinator expression, using only application together with the constants `I`, `K`,
  `S`
  and the constants already occurring in `t` -- exactly Scott's challenge.

```

The completeness theorem is `bracket\_spec`:

```

'''
(bracket t).denote, applied to x, equals t.denote x      for every x.
'''

```

i.e. the variable-free combinator expression `bracket t` denotes precisely the function `fun x. t`. By induction on `t` this is driven by the three combinator identities, turning the table around as Scott asks.

Everything is **data**; the combinators are built from `idMap`, `curry`, `proj`, `eval` and are choice-free.

/-! ### Syntax of `fun`-bodies with one free variable, and of variable-free combinator
expressions. -/

/-- `Poly X A` : an open term of type `A` with a single free variable of type `X`. Constructors:
the variable, a closed constant (any element of any domain -- "enough combinators available"),
and
application. This is the syntax of `fun`-bodies whose abstraction we want to eliminate. -/
inductive Poly (X : Dom) : Dom -> Type 1 where
  /-- The free variable. -/
  | var : Poly X X
  /-- A closed constant `c : |A|` (in particular any available combinator). -/
  | con {A : Dom} (c : A.sys.Element) : Poly X A
  /-- Application `f(a)`. -/
  | app {A B : Dom} (f : Poly X (A.arrow B)) (a : Poly X A) : Poly X B

/-- `CL A` : a variable-free combinator expression of type `A`. The only constructors are
constants and application, so application (`sigma(tau)`) is the sole mode of combination. -/
inductive CL : Dom -> Type 1 where
  /-- A closed constant. -/
  | con {A : Dom} (c : A.sys.Element) : CL A
  /-- Application `f(a)`. -/
  | app {A B : Dom} (f : CL (A.arrow B)) (a : CL A) : CL B

/-- The denotation of an open term: the body as a function of its free variable. -/
def Poly.denote {X : Dom} : {A : Dom} -> Poly X A -> X.sys.Element -> A.sys.Element
| _, .var, x => x
| _, .con c, _ => c
| _, .app f a, x => (toApproxMap (f.denote x)).toElementMap (a.denote x)

```

```

/-! ### Bracket abstraction. -/

/-- **Bracket abstraction.** Turn an open body `t` (a `fun`-body with one free variable) into
a
*variable-free* combinator expression denoting `fun x.t`, using only application and the
combinators
`I`, `K`, `S` together with the constants already occurring in `t`:

* `[x] x`      = I`
* `[x] c`      = K(c)`      (`c` a constant / closed term)
* `[x] (f a)`  = S([x]f)([x]a)`
-/
def bracket {X : Dom} : {A : Dom} -> Poly X A -> CL (X.arrow A)
| _, .var => .con (Ielem X)
| _, .con c => .app (.con (Kelem _ X)) (.con c)
| _, .app f a => .app (.app (.con (Selem X _ _)) (bracket f)) (bracket a)

/-- **Combinatory completeness (Exercise 5.8, Scott 1981, PRG-19).** The variable-free
combinator
expression `bracket t` denotes exactly the function `fun x.t`: applied to any `x`, it yields `t
.denote x`.

Thus, with `I`, `K`, `S` (and the constants of `t`) available, every `fun`-abstraction can be
defined
by combining combinators using application as the only mode of combination -- Scott's "turning
of the
tables". -/
theorem bracket_spec {X : Dom} {A : Dom} (t : Poly X A) (x : X.sys.Element) :

/-!
# Exercise 5.9 (Scott 1981, PRG-19, Lecture V)

```

Suppose $f, g : ? \rightarrow ?$ are approximable and $f \text{ comp } g = g \text{ comp } f$. Then:

```
* `f` and `g` have a least common fixed point  $x = f(x) = g(x)$  (`commuting_least_common_fixed`);
* if in addition  $f(\text{False}) = g(\text{False})$ , then  $\text{fix}(f) = \text{fix}(g)$  (`fixElement_eq_of_commuting_bot`);
* in particular  $\text{fix}(f) = \text{fix}(f?)$  (`fixElement_iterTwice`).
```

Construction. Let $a = \text{fix}(f)$. Commutation makes $g(a)$ a fixed point of f ($f(g(a)) = g(f(a)) = g(a)$), so $a \sqsubseteq g(a)$, and Exercise 4.7 produces the least fixed point of g above a , namely $x = \sqsup_n g^n(a)$. Each $g^n(a)$ is again a fixed point of f (induction + commutation), and f preserves the directed union, so $f(x) = x$: x is a common fixed point. Any common fixed point w satisfies $a = \text{fix}(f) \sqsubseteq w$ and $g(w) \sqsubseteq w$, so $x \sqsubseteq w$ by Exercise 4.7's leastness.

For the second part, commutation gives $g(f^n(\text{False})) = f^{n+1}(\text{False})$ once $g(\text{False}) = f(\text{False})$, so $g(\text{fix } f) = \sqsup_n f^{n+1}(\text{False}) = \text{fix } f$; symmetrically $f(\text{fix } g) = \text{fix } g$, whence $\text{fix } f = \text{fix } g$ by leastness.

All maps and elements are choice-free; the equalities use only the order on $|?|$.

# Exercise 5.10 (Scott 1981, PRG-19, S5) -- the smash product and the strict function space
```

```
> Suppose `?_0` and `?_1` are neighbourhood systems over disjoint sets `Delta_0` and `Delta_1`.
  Define the
> *smash product* `?_0 ? ?_1` with neighbourhoods
> `{Delta_0 U Delta_1} U {X U Y | X in ?_0 ? {Delta_0} and Y in ?_1 ? {Delta_1}}`.
> Show that this *is* a neighbourhood system. Define `(?_0 -> False ?_1)` so that `|?_0 ->
  False ?_1|` consists
> exactly of the *strict functions*. By introducing appropriate combinators, show that
> `(?_0 -> False (?_1 -> False ?_2))` and `((?_0 ? ?_1) -> False ?_2)` are isomorphic.
```

We model the disjoint union of token sets by the **sum type** `a ? b`, exactly as for the ordinary product `(Domain/Neighborhood/Product.lean)`, reusing `prodNbhd X Y = Sum.inl '' X U Sum.inr '' Y` and its algebra `(prodNbhd\_inter`, `prodNbhd\_subset\_iff`, `prodNbhd\_injective`).

This file is organised as follows.

```
* **The smash product** `smash V_0 V_1` (`S smash`): a genuine neighbourhood system. The
  neighbourhoods
  are the master `Delta_0 U Delta_1` together with the *proper* product neighbourhoods `X U
  Y` whose factors are
  both *proper* (`X != Delta_0`, `Y != Delta_1`). Closure under consistent intersection is
  the new content: the
  consistency witness rules out the degenerate cases, and a proper factor stays proper under
  intersection.
* **The smash collapses bottoms** (`S elements`): the element `smashPair x y` (the strict
  pairing) and
  the order-isomorphism showing `|?_0 ? ?_1|` is the *smash* of the pointed domains -- every
  element is
  either `False` or a pair `` of *non-False* elements.
* **The strict function space** `strictFun V_0 V_1` (`S strict`): a neighbourhood system whose
  elements
  are exactly the *strict* approximable maps (`IsStrict f`, i.e. `f(False) = False`). We
  realise it as the
  function space generated only by step neighbourhoods `[X, Y]` with *proper* input `X`, and
  prove the
  representation `strictFunEquiv : |?_0 -> False ?_1| ?o {f | IsStrict f}`.
* **The adjunction** (`S iso`): the "appropriate combinators" Scott asks for -- a strict curry
  `smashCurryMap` and strict uncurry `smashUncurryMap` -- assembled into the order-isomorphism
  `smashCurryEquiv : ((?_0 ? ?_1) -> False ?_2) ?o (?_0 -> False (?_1 -> False ?_2))`. The
  decisive computation is
  `section_uncurry_rel` : `g(<x, y>) = curryFalse(g)(x)(y)`, with the boundary (a master factor
  ) handled
  by strictness -- exactly the bottom-gluing the smash performs.
```

The **data** (`smash`, `strictFun`, `smashCurryMap`, `smashUncurryMap`) and the representation `strictFunEquiv` are **choice-free** (`#print axioms subseq {propext, Quot.sound}); `Classical.choice` enters only the `smashCurryEquiv` **proof**, through the genuinely-classical `X = Delta_0?` / `Y = Delta_1?` boundary case analysis.

/-! ### The smash collapses bottoms: the strict pairing `?`.

The smash identifies all elements that have a `False` in either coordinate. We realise this by
the *strict
pairing* `smashPair x y` : when both `x, y` are non-`False` it is the genuine pair ``, and
when either
is `False` it collapses to `False` (`smashPair_eq_bot_iff`). Every element of `|?_0 ? ?_1|`
arises this way. -/

/-- The *strict pairing* `?` : the filter generated by the proper product neighbourhoods
`X U Y` with `X` in `x ? {Delta_0}`, `Y` in `y ? {Delta_1}` (plus the master). When either `x`
or `y` is `False` (i.e.
contains only its master), this collapses to `False`. -/

/-! ### The strict function space `(?_0 -> False ?_1)`.

A map `f : ?_0 -> ?_1` is strict when `f(False) = False`. In relational terms (since `f(False)` is the filter
`{Y ? Delta_0 f Y}`), this says `f` relates the master input `Delta_0` only to the master
output `Delta_1`:
`Delta_0 f Y ? Y = Delta_1`.

We realise `(?_0 -> False ?_1)` as the function space whose tokens are the strict
approximable maps and
whose neighbourhoods are the non-empty finite intersections of step sets `[X, Y] = {f ? X f Y}`. The
crucial point -- making `|?_0 -> False ?_1|` consist exactly of the strict functions -- is
automatic: a step
`[Delta_0, Y]` with `Y != Delta_1` contains no strict map, so it is empty, hence never a
neighbourhood; thus no
filter can force a non-strict value at `False`. The representation `strictFunEquiv` then
mirrors
Theorem 3.10. -/

/-- A map is strict when `f(False) = False`. Relationally: `f` sends the master input
only to the master
output. -/

are the same as strict maps into a strict function space. We realise the iso with the "
appropriate
combinators" Scott asks for -- a *strict curry* and *strict uncurry* -- connected by the
computation
`g(<x, y>?) = (curry g)(x)(y)`.

The decisive computation is `smashPair_principal_apply`: for *proper* `X, Y`, applying `g` to
the
strict pairing of the principal elements is the same as `g` relating the proper neighbourhood
`X U Y`. At the bottom (a master factor) the strict pairing collapses to `False`, where
strictness forces
the master output -- exactly the gluing the smash performs. -/

variable {V_2 : NeighborhoodSystem ?}

/-- Every smash neighbourhood is a product neighbourhood `A U B` (the master is `Delta_0 U
Delta_1`). -/
theorem smash_mem_prodNbhd_form {W : Set (a ? b)} (hW : (smash V_0 V_1).mem W) :

# Exercise 5.11 (Scott 1981, PRG-19, S5) --  $D^\infty$  as stacks; stack combinators

Regarding  $D^\infty = \text{iterSys } D$  (Exercise 3.16) as (bottomless) *stacks* of elements of  $D$ ,
Scott asks
for combinators with the obvious meanings

'''
head :  $D^\infty \rightarrow D$ ,      tail :  $D^\infty \rightarrow D^\infty$ ,      push :  $D \times D^\infty \rightarrow D^\infty$ 
'''

then for  $\text{diag} : D \rightarrow D^\infty$  with  $\text{diag}(x) = \langle x \rangle_n$  (every component equal to  $x$ ), defined
by the
recursion  $\text{diag}(x) = \text{push}(x, \text{diag}(x))$ , and finally a combinator

'''
map :  $(D \rightarrow D)^\infty \times D \rightarrow D^\infty$ ,      map( $\langle f_n \rangle$ ,  $x$ ) =  $\langle f_n(x) \rangle_n$ .
'''

We build  $\text{head}$ ,  $\text{tail}$ ,  $\text{push}$  from the order-isomorphism  $\text{iterProdIso} : D^\infty \cong D \times D^\infty$ 
of
Exercise 3.16 (so  $\text{unfold} = \text{ofIso iterProdIso}$ ,  $\text{fold} = \text{ofIso iterProdIso.symm}$ ), and obtain
the
**stack laws**

*  $\text{head\_push} : \text{head}(\text{push}(x, s)) = x$ ,
*  $\text{tail\_push} : \text{tail}(\text{push}(x, s)) = s$ ,
*  $\text{push\_head\_tail} : \text{push}(\text{head } z, \text{tail } z) = z$ ,

together with the component readings  $\text{head } z = z_0$  and  $(\text{tail } z)_n = z_{n+1}$ .

 $\text{diag}$  and  $\text{map}$  are defined as least fixed points (Theorem 4.1/4.2); for  $\text{diag}$  we prove Scott
's
emphasised property that all components equal  $x$  ( $\text{component\_diag}$ ), and for  $\text{map}$  that
the
 $n$ -th component is  $f_n(x)$  ( $\text{component\_map}$ ).

The only classical input is what is inherited from  $\text{iterProdIso}$  /  $\text{fixMap}$  and the project's
 $\text{Element.ext}$  machinery.

# Exercise 5.12 (Scott 1981, PRG-19, S5) -- the `while` combinator

Given a domain `D`, a *predicate* `p : D -> T` (into the truth domain of Example 1.2) and an
*update* `f : D -> D`, Scott's `while`-loop

'''
while p do f
'''

is the function `D -> D` that keeps applying `f` while `p` holds. It is characterised as the
least
solution `w : D -> D` of the recursion

'''
w(x) = cond(p(x), w(f(x)), x).
'''

We realise this *semantically* inside the approximable-map framework: the right-hand side, read
as
a function of the unknown `w`, is an approximable operator

'''
Wop : (D -> D) -> (D -> D), Wop(w) = fun x. cond(p(x), w(f(x)), x),
'''

built from the conditional `cond` of Exercise 3.26, evaluation `eval`, the projections, pairing
and
composition. The loop is then `whileFix = fixElement Wop`, the least fixed point of `Wop`
(Theorem 4.1), and `whileMap = toApproxMap whileFix : D -> D` the approximable function it
denotes.

We prove:

* `whileMap_rec` -- the defining recursion `w(x) = cond(p(x), w(f(x)), x)`;
* `whileMap_true` -- if `p(x) = true` then `w(x) = w(f(x))` (loop body runs);
* `whileMap_false` -- if `p(x) = false` then `w(x) = x` (loop exits);
* `whileMap_bot` -- if `p(x) = False` then `w(x) = False` (divergent test diverges);
* `whileMap_least` -- leastness: any `w` satisfying the recursion dominates `whileMap`.

Everything is choice-free in spirit; the only classical input is inherited from `cond`/`T`
(Example 1.2) and the project's `Element.ext` / `ext_of_toElementMap` machinery.

# Exercise 5.13 (Scott 1981, PRG-19, Lecture V) -- a one-one pairing `num : N x N -> N`

> Prove the existence of a one-one function `num : Nat x Nat -> Nat` such that
>
> * `num(0, 0) = 0`,
> * `num(n, m+1) = num(n+1, m) + 1`,
> * `num(n+1, 0) = num(0, n) + 1`.
>
> Draw a picture (an infinite matrix) for the function and find a closed form for its values.
> Use the function to prove the isomorphism of the domains `P N`, `P(N x N)`, `P N x P N`.

## The picture

Reading `n` down the rows and `m` across the columns, the three recurrences walk the anti-diagonals
`n + m = const`, climbing one step (`+1`) each move and jumping to the start of the next
diagonal at
the left edge:

...
      m=0  m=1  m=2  m=3
n=0      0   2   5   9
n=1      1   4   8
n=2      3   7
n=3      6
...

## The closed form

```

On the anti-diagonal $s = n + m$ the values run $T(s), T(s)+1, \dots, T(s)+s$ where $T(s) = s(s+1)/2$

is the s -th triangular number; the offset within the diagonal is exactly m . Hence

$$\text{num } n \ m = (n + m) * (n + m + 1) / 2 + m$$

-- the **Cantor pairing function**. We take this as the definition (`num`), verify Scott's three recurrences (`num_zero_zero`, `num_succ_right`, `num_succ_left`), and prove it is one-one (`num_injective`). In fact it is a **bijection**: we build a choice-free inverse `unnum` (iterate the diagonal walk `nextCell` from `(0,0)`) and package the bijection as `numEquiv : Nat x Nat ? Nat`.

The domain isomorphisms

Following Exercise 4.17, the power-set domain `P A` is modelled by the complete lattice `(Set A, subseq)`.

Order-isomorphisms of these domains are then induced by bijections of the index types (`setCongr`). Since `Nat x Nat ? Nat` (via `numEquiv`) and `Nat ? Nat ? Nat` (Mathlib's `Equiv.natSumNatEquivNat`), all three domains are isomorphic:

```
`P N  ~= P(N x N)`      (`PN_orderIso_PNN`),
`P N  ~= P N x P N`     (`PN_orderIso_prod`),
`P(N x N) ~= P N x P N`  (`PNN_orderIso_prod`).
```

Everything (including `numEquiv` and the order-isomorphisms) is **choice-free** (`#print axioms subseq {prope, Quot.sound}`).

# Exercise 5.14 (Scott 1981, PRG-19, Lecture V) -- the graph model `P?`

> Using the pairing function of Exercise 5.13, code finite sequences by
> `[n_0, ..., n_k] = num(n_0, [n_1, ..., n_k])` and define
>
> `fun(u)(x) = {m ? exists n_0 ... n_{k-1} in x, [n_0+1, ..., n_{k-1}+1, 0, m] in u}`,
> `graph(f) = {[n_0+1, ..., n_{k-1}+1, 0, m] ? m in f({n_0, ..., n_{k-1}})}`.
>
> Show `fun comp graph = fun f.f` (for continuous `f`) and `graph comp fun supseteq fun x
    .x`.

```

Following Exercises 4.17 and 5.13, the power-set domain `P?` is modelled by the complete lattice
 `(Set Nat, subseq)`.

The coding

The decisive device is the **tag**

```

tag [n_0, ..., n_{k-1}] m = [n_0+1, ..., n_{k-1}+1, 0, m] = num(n_0+1, ... num(n_{k-1}+1, num
  (0, m))...)`,
defined by

```

```

tag [] m = num 0 m, tag (n :: ns) m = num (n+1) (tag ns m).

```

It is a **bijection** `(List Nat) × Nat → Nat` : injectivity (`tag_injective`) is an induction using

`num_injective`, and surjectivity (`tag_surjective`) is strong induction on the value, decreasing

because `num (n+1) b > b` (`num_succ_left_gt`) -- the head's first coordinate is either `0` (stop,

emit `m`) or `>= 1` (peel one entry and recurse on a strictly smaller code).

```

## The maps

With `entries ns = {n ? n in ns}` the finite set of entries of a list:

* `Fun u x = {m ? exists ns, (forall n in ns, n in x) /\ tag ns m in u}`,
* `Graph f = {c ? exists ns m, c = tag ns m /\ m in f (entries ns)}`.

`fun comp graph = id` holds only for continuous maps, captured by
`IsApprox f := Monotone f /\ (finite approximation)`. We prove:

* `Fun_Graph` : `Fun (Graph f) x = f x` for `IsApprox f` -- the reflexive equation `fun comp
  graph = fun f.f`;
* `id_le_Graph_Fun` : `u subseq Graph (Fun u)` -- the inclusion `graph comp fun supseq
  fun x.x` (genuinely `supseq`, since
  reorderings/duplications of a list with the same `entries` give other codes in `Graph (Fun u)`);
* `Fun_isApprox` : every `Fun u` is itself `IsApprox`, so `fun` lands in the continuous maps.

Everything is choice-free (`#print axioms subseq {proptext, Quot.sound}`).

import Mathlib.Algebra.FreeMonoid.Basic

/-!
# Exercise 5.15 (Scott 1981, PRG-19, Lecture V) -- free-semigroup powerset and Arden's lemma

```

```

> (For algebraists.) Regard  $\{0,1\}^*$ ,  $\{?, *\}$  as the free semigroup on two generators. The
  powerset
>  $\{0,1\}^*$  is a domain (Exercise 4.17). For a word  $e$  set  $e^* = \{?, e, e?, \dots\}$ .
>
> (1) The least fixed point of  $z = \{e\} * z \cup \{e\}$  is  $z = e^*\{e\}$ .
> (2) (David Park) The least solution of
>  $x = a * x \cup b * y \cup c$ ,  $y = b * x \cup a * y \cup d$ 
> is  $x = (a \cup b * a^* b)^* (c \cup b * a^* d)$ , where  $z^* = ? \cup z^* z$ .

```

Following Exercise 4.17, the powerset domain $\mathcal{P} S$ of a monoid S is the complete lattice $(\text{Set } S, \text{subseq})$ with pointwise product $s * t = \{u * v \mid u \in s, v \in t\}$ (Set.mul , open Pointwise).

Both parts are facts about the Kleene algebra $(\text{Set } S, \cup, *, \{\}, \{1\})$ and hold for any monoid;

we prove them with S a general Monoid and specialise part (1) to $S = \text{FreeMonoid Bool} = \{0,1\}^*$.

Choice discipline

Mathlib's Set -level multiplicative lemmas (mul_assoc , Set.union_mul , Set.mul_union , $\text{Set.singleton_mul_singleton}$), the order lemmas Set.subset_iUnion / Set.iUnion_subset , $\text{Set}^{\text{power}}$ (pow_succ), $\text{Submonoid.mem_powers_iff}$, and Monotone over Set all depend on Classical.choice in this toolchain (they route through Set.image2 / CompleteLattice choice-using machinery). Every membership iff (Set.mem_mul , Set.mem_union , Set.mem_one , $\text{Set.mem_singleton_iff}$) and every element-level monoid lemma is choice-free. So we reprove the small slice of Kleene algebra we need (smul_assoc , sunion_mul , smul_union) at the membership level, define star by an explicit recursion (kpow) rather than $?_n z?$, and phrase Arden's lemma without Monotone -- keeping everything **choice-free** ($\# \text{print axioms subseq \{propext, Quot.sound\}}$).

# Exercise 5.16 (Scott 1981, PRG-19, Lecture V) -- `neg`, `merge` and `d` on `C`

Returning to Example 4.4 (the domain `C` of finite or infinite binary sequences), this module
gives
fixed-point/recursive definitions of three maps and verifies their characterizing equations:

* **`tail : C -> C`** (`tail(bx) = x`, `tail(?) = False`) -- Scott's predecessor analogue,
the item left to
the reader in Example 4.4, built here with the head-test combinator `Exercise419.liftC`.
* **`neg : C -> C`** with `neg(0x) = 1*neg(x)`, `neg(1x) = 0*neg(x)` -- bit-complement. We
solve the
recursion in closed form via `liftC` (`neg(sigma) = (flip sigma)`, `flip = List.map not`),
prove the
recursion equations `neg_cons_false`/`neg_cons_true` (so it is the solution), and prove
Scott's
involution law **`neg(neg x) = x` for all `x` in `|C|`** (`negMap_negMap`) -- using that an
approximable
map is determined by its values on the finite elements `sigmaFalse`, `sigma` (Exercise 2.8,
`eq_of_toElementMap_principal`), so it suffices to check the two-fold complement on those,
where it
is `flip comp flip = id`.
* **`d : C -> C`** (`d(?) = ?`, `d(0x) = 00*d(x)`, `d(1x) = 11*d(x)`) -- the bit-doubling map
of
Example 4.4, again via `liftC` (`d(sigma) = double sigma`).
* **`merge : C x C -> C`** with `merge(?x, ?y) = ?*?*merge(x, y)` -- bit-interleaving.
Built directly as
an approximable map out of `prod C C` from an explicit interleave value function `mergeVal`.
The
boundary that Scott flags (`merge(?y, ?x)` etc.) is resolved by the unique *monotone*
convention
(`merge(?y, ?x) = ?`, `merge(?x, ?y) = ?False` once `?y` runs out), the only choice compatible
with
approximability. We prove the recursion equation and **`merge(x, x) = d(x)`** (`mergeMap_diag`
`).

All *data* (`tail`, `negMap`, `dMap`, `mergeMap`) is **choice-free** (`#print axioms subseq
{propeq,
Quot.sound}`); equalities of maps go through `eq_of_toElementMap_principal` (classical, exactly
like
the project's `ext_of_toElementMap`).

The Thue-Morse properties of `t = 0*merge(neg t, tail t)` (its digit-sum-mod-2 description and
overlap-freeness) are real combinatorics-on-words and are left as a separate follow-up.

# Exercise 5.16 follow-up (Scott 1981, PRG-19, Lecture V) -- the Thue-Morse sequence `t`

The unfinished tail of Exercise 5.16. Returning to the domain `C` of finite/infinite binary
sequences (Example 4.4), Scott studies the element

`t = 0*merge(neg t, tail t)`,

the least fixed point of ` $?(x) = 0*merge(neg x, tail x)$ `, and (Lambek's observation) identifies
its
`n`-th digit with the parity of the binary digits of `n` -- the Thue-Morse sequence.

This module formalizes:

* Step 0 -- the element and its unfolding. `tElt := ?.fixElement` and `tElt_unfold` proving
  ` $t = 0*merge(neg t, tail t)$ `.
* The Thue-Morse morphism `expand` (the substitution ` $0 \mapsto 01$ `, ` $1 \mapsto 10$ `) and the
  key bridge
  ` $\Phi_{strBot\_expand}$ : applied to a partial element ` $(0sigma)False$ `, the operator ` $?$ ` is
  exactly `expand`.
  Consequently the finite approximants of the least fixed point are ` $??^{+1}(False) = (expand
  ?[0])False$ `
  (iterElem_succ_eq).
* The parity bit-function `tm` with  $tm\ n = ?$  (binary digits of  $n$ ) (via Nat.bits), its
  recurrences  $tm\ (2n) = tm\ n$ ,  $tm\ (2n+1) = not\ tm\ n$ , and the bridge expand_iterate_eq
  showing the

```

```

    approximant strings are precisely the Thue-Morse parity prefixes `tmList (2?)`.
* **Property (a) -- the digit characterization.** `tElt_mem_cone_iff`: a finite string `sigma`
  is a prefix
  of `t` **iff** `sigma` is the length-`sigma.length` Thue-Morse prefix (`sigma = tmList sigma.
    length`); and the
  digit reading `tElt_digit : (tmList n ++ [tm n])False <= t`, i.e. the `n`-th digit of `t`
  is `tm n`,
  the parity of the binary digits of `n` (Lambek).

The `tElt` *data* is choice-free; the `Prop`-level digit facts may use `Classical.choice` (
  through the
project's `eq_of_toElementMap_principal` and the truth-domain primitives), exactly like the
  existing
uniqueness lemmas. Overlap-freeness (property (b)) is a self-contained word-combinatorics
  theorem and
lives in its own module.

# Exercise 5.16 follow-up (Scott 1981, PRG-19, Lecture V) -- overlap-freeness of `t`

The second Thue-Morse property Scott asks for: `t` is overlap-free, `t` != `u*a*a*v` for
any
finite `u` and nonempty `a`. This is a self-contained theorem of combinatorics on words (Thue
1912);

```

it uses **no domain theory** (only the parity recurrences $tm(2n) = tm\ n$, $tm(2n+1) = not\ tm\ n$ of the bit-function `tm` from `Exercise516ThueMorse`) and has no leverage from Mathlib, so it is proved from scratch here.

We phrase an **overlap** of period $p \geq 1$ at offset i as a factor of length $2p+1$ with period p : `Overlap i p := 1 <= p /\ forall k <= p, tm (i+k) = tm (i+p+k)`. The main theorem `no_overlap` shows no overlap exists, and `overlap_free` is Scott's literal cube form `t != u*a*a*a*v` (an overlap is weaker than a cube, so the cube form follows).

The proof is the classical descent: the two base facts are **no three consecutive equal symbols** (`no_three_consec`, the period-1 case) and a direct period-3 computation; an even period $2q$ contracts to a period- q overlap via the substitution structure, and an odd period ≥ 5 forces a run of three equal symbols.

# Example 6.1 (Scott 1981, PRG-19, S6) -- the tree algebra `D^S` and the domain equation
`D^S` ~ `D + (D^S x D^S)`

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981),
Lecture VI,
*Introduction to domain equations*. Starting from a fixed domain `D` (a neighbourhood system
over `Delta`)
Scott iterates the product `D x D` *indefinitely* and collects all the iterates into a **
single**
domain `D^S`, the *tree algebra* over `D`. The construction:

* the tokens of `D^S` live in `Gamma = {1,2}* 0 Delta` -- a finite `{1,2}`-path (here a `List
  Bool`, `true = 1`,
  `false = 2`) followed by a separator `0` and a `D`-token in `Delta`. We model this as `List
  Bool x a`
  with the master neighbourhood `Gamma = {t | t.2 in Delta}`;
* the neighbourhoods of `D^S` are the **least** family containing (i) `Gamma`, (ii) `0X = {( [],
  a) ? a in X}`
  for `X in ?`, and (iii) `1P U 2Q` for `P, Q in ?^S`. This is the inductive predicate `
  MemS`.

The heart of the example is Scott's verification that `D^S` is a neighbourhood system: closure
under
consistent intersection, proved by induction on the way `X` was put into `D^S`, using the
standing
assumption `{ } notin ?` (passed as `hD : forall X, ?.mem X -> X.Nonempty`). The pay-off is
the **domain
equation**

`D^S` ~ `D + (D^S x D^S)`,

formalized as the order-isomorphism `dsharpEquiv : (Dsharp D hD).Element ?o (sum D (prod ...
...).Element`,
i.e. `Dsharp D hD ~ ? sum D (prod (Dsharp D hD) (Dsharp D hD)) ...`.

We use the project's `+` (`sum`, Exercise 3.18) and `x` (`prod`, Definition 3.1). All *data*
is
choice-free (`#print axioms subseq {propeq, Quot.sound}`).

# Example 6.2 (Scott 1981, PRG-19, S6) -- `B` and `C` as solutions of domain equations

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981),
Lecture VI,
*Introduction to domain equations*. Scott observes that the staple examples `B` (binary
sequences,
Example 1.B) and `C` (finite-or-infinite binary sequences, Example 4.4) satisfy *domain
equations*:

`B`  ~=  B + B`,    `C`  ~=  {{{?}} + C + C`,

where, "if we liked", both systems can be presented over `{0,1}*` as the least families

`B` = {Sigma*} U {0X ? X in B} U {1X ? X in B}`,
`C` = {Sigma*} U {{{?}} U {0X ? X in C} U {1X ? X in C}`.

```

This module formalizes the $B \approx B + B$ half. (See `Example62C.lean` for `C`'s three-way equation $C \approx ? + C + C$.)

The point of the equation is that a neighbourhood of `B` is either the master `Sigma*` (`= cone []`), a `0`-prefixed copy `0X` (`= embBit false X`), or a `1`-prefixed copy `1X` (`= embBit true X`) -- exactly the three shapes that build the sum `B + B` (Exercise 3.18): the fresh basepoint, the left copy `0X`, and the right copy `1X`. We exhibit the order-isomorphism `bbEquiv : |B| ≃o |B + B|` directly from the filter maps `toBB` (forward) / `fromBB` (inverse), mirroring `Example61.dsharpEquiv`.

All `*data*` is choice-free (`#print axioms subseteq {propeq, Quot.sound}`).

# Example 6.2 (Scott 1981, PRG-19, S6) -- `C  ~=  {{?}} + C + C`

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981),
Lecture VI.
This module formalizes the second domain equation of Example 6.2, for the system `C` of finite
or
infinite binary sequences (Example 4.4):

`C  ~=  {{?}} + C + C`,

where `{{?}} = ?` is the one-point (unit) domain (Exercise 3.15). Presented over `{0,1}*`,

`C = {Sigma*} U {{?}} U {0X ? X in C} U {1X ? X in C}`,

so a neighbourhood of `C` is the master `Sigma*` (= cone  $[]$ ), the terminator `{?} = [[]]`, a
`0`-copy
`0X = embBit false X`, or a `1`-copy `1X = embBit true X`. These four shapes are exactly those
of a
**three-way separated sum** `? + C + C`: a fresh basepoint, plus one `?`-copy (the lone `{?}`),
plus
two `C`-copies.

Crucially this is a genuine *three-way* sum: nesting the binary sum `(? + (C + C))` would
introduce a
spurious extra bottom element (the inner sum's basepoint) with no counterpart in `C`. So we
first build
the three-way separated sum `sum3` (mirroring Exercise 3.18), then exhibit the order-
isomorphism
`ccEquiv : |C| ?o |? + C + C|`.

All *data* is choice-free (`#print axioms subseq {propext, Quot.sound}`).

# Example 6.2 (Scott 1981, PRG-19, S6) -- the generalisation `A ~?= A? + A?`

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981),
Lecture VI.
After the staple equations `B ~?= B + B` and `C ~?= {{{?}} + C + C` (see `Example62.lean`/`
Example62C.lean`),
Scott proposes "a simple, yet interesting generalization of `B`": for any `n`, the domain
equation

`A ~?= A? + A?`,

where `A?` is the `n`-fold cartesian power. He solves it concretely over `Sigma* = {0,1}*` as
the least
family

`A = {Sigma*} U ?_{i in {0,1}} { i ?_{j<n} 1?0 X_j ? X_j in A for all j < n }`,

so a neighbourhood (other than the master `Sigma*`) is a tag bit `i` (Scott's `+/?`, here `true`
`/`false`)
followed by `n` slots, slot `j` reached behind the self-delimiting prefix `1?0`. An element of
`A`
(other than `False`) is thus `

```

For $n = 1$ this recovers $B \approx B + B$ (one slot per copy); the tree picture and the automata theory aside (eventually-periodic trees $\leftrightarrow$ regular events) are formalised in `Example62Regular.lean`.

All `*data*` is choice-free (`#print axioms subseq {prope, Quot.sound}`).

# Example 6.2 (Scott 1981, PRG-19, S6) -- eventually-periodic trees and regular events

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19 (1981),
Lecture VI,
*Introduction to domain equations*. After exhibiting the generalised domain equation  $A \approx A? + A?$ 
(formalised in Example62A.lean), Scott closes Example 6.2 with a casual aside connecting
his
infinite  $?^*$ -labelled  $n^*$ -ary trees to automata theory:

> "We say that a (total) tree  $a$  is eventually periodic iff the set  $\{\text{asigma } ? \text{ sigma in Sigma}^*\}$  is finite.
> The result is that the 'language'  $L_a = \{\text{sigma in Sigma}^* \mid \text{pos}(\text{asigma}) = \text{true}\}$ 
corresponding to an eventually
> periodic tree is always a regular event of automata theory, and every such language has
this form.
> In fact,  $a$  just represents the initial state of an automaton, and  $\text{asigma}$  represents the
state after
> 'reading' a tape  $\text{sigma}$ ."
```

This file makes that remark precise and *proves* it. Scott's total trees over $\text{Sigma} = \{0, \dots, n-1\}$ are exactly the functions $a : \text{Sigma}^* \rightarrow \text{Bool}$ assigning a $?^*$ label (pos^*) to every node, addressed by a finite selector sigma in Sigma^* . The *subtree* operation $\text{sigma} \mapsto \text{asigma}$ is Scott's selector recursion $a? = a$, $a(\text{isigma}) = (a_i)\text{sigma}$; its *language* L_a is the set of selectors landing on a $^+$ node.

The two halves of Scott's claim are exactly the two halves of the *Myhill-Nerode theorem*: a tree is eventually periodic (finitely many distinct subtrees) iff its language has finitely many *left quotients* iff (Myhill-Nerode, `Language.isRegular_iff_finite_range_leftQuotient`) the language is regular. The bridge is that the subtree asigma *is* the left quotient $\text{sigma}^{-1} L_a$: reading the tape sigma moves the automaton to the residual language, which is precisely the subtree at sigma .

This is a Prop^* -level result (about regularity), so `Classical.choice` is unobjectionable here; the content is entirely the combinatorics-on-words / automata correspondence, orthogonal to the neighbourhood-system machinery.

# Lecture VI -- Definitions 6.3-6.5 (Scott 1981, PRG-19): functors,  $T$ -algebras, initial
algebras

To state domain equations  $D \approx T(D)$  and single out their canonical solutions, Scott
introduces
"a small amount of the terminology of category theory" and stresses that the next few
definitions
"could be given for any category". This module sets up a small, self-contained category
abstraction
and formalises that vocabulary:

* Definition 6.3 -- a functor  $T$  on a category into itself (an endofunctor),
preserving
identities and composition.
* Definition 6.4 -- a  $T$ -algebra  $k : T(E) \rightarrow E$  and a homomorphism of  $T$ -algebras.
* Definition 6.5 -- an initial  $T$ -algebra: one with a unique homomorphism into every
algebra.

Everything is generic over an arbitrary  $\text{Category}$ , exactly as Scott emphasises. As Scott also
notes
in the prose preceding Definition 6.3 ("[the systems] form quite an interesting category with
respect
to the approximable maps"), the neighbourhood systems and approximable maps of the project are
a
category; that instance ( $\text{DomainObj}$ ) is provided here as a witness that the abstract
definitions are
not vacuous.

Auxiliary categorical lemmas (identity and composition of algebra homomorphisms,  $\text{Iso}$ ) needed
for
Propositions 6.6 and 6.7 are developed here as well.

All definitions and lemmas are constructive and choice-free
(#print axioms subseq {propxt, Quot.sound}); the underlying composition laws are the
project's
idMap_comp/comp_idMap/comp_assoc (Theorem 2.5).

## Why a bespoke  $\text{Category}$  rather than Mathlib's  $\text{CategoryTheory.Category}$ ?

```

Mathlib *does* have a fully developed category theory: ``CategoryTheory.Category`` (structurally identical to the class below -- separate object/morphism universes, ``Hom``, ``id``, ``comp``, and the three laws), functors ``C ? D``, ``Iso``, ``CategoryTheory.Endofunctor.Algebra``/``Algebra.Hom`` with the category of algebras, ``Limits.IsInitial``, and even Lambek's lemma as ``Endofunctor.Algebra.Initial.strInv`` / ``left_inv`` / ``right_inv``. So Mathlib is *expressive enough* to state every one of Definitions 6.3-6.5 (and Propositions 6.6-6.7) verbatim -- it is not a question of missing vocabulary.

It is nonetheless the wrong tool *here*, and the reason is this project's headline invariant, not taste. The trade-off was checked empirically:

```
* The bare instance is fine: a `Category DomainObj` built on `ApproximableMap` (Theorem 2.5
  laws)
  is choice-free, `#print axioms = [proptext, Quot.sound]`.
* But the only reason to import Mathlib's hierarchy is to reuse its downstream content --
  functor
  algebras and the initial-algebra fixed-point theorem -- and that content is choice-bound:
  `Mathlib.CategoryTheory.Endofunctor.Algebra.Initial.left_inv` (the inverse half of Lambek's
  lemma,
  i.e. Scott's Proposition 6.7) reports `[proptext, Classical.choice, Quot.sound]`, because
  Mathlib's
  `IsInitial` rides on the `Limits` framework.
* By contrast, the project's own `initialIso` (Proposition 6.6) and `lambek` (Proposition 6.7),
  built
  on the class below, depend on no axioms whatsoever (`#print axioms` reports "does not
  depend on
  any axioms").
```

So adopting Mathlib would force one of two losing choices: (a) consume its initial-algebra API and thereby inject ``Classical.choice`` into the project's flagship Lecture VI results, breaking the ``#print axioms subseq {proptext, Quot.sound}`` discipline that is the whole point; or (b) take only the bare class and re-prove 6.6-6.7 by hand anyway -- paying a heavy transitive import and the ``?`` (diagrammatic, `"f` then `g`"`) vs ``?`` (Scott's `"`g` after `f`"`) convention clash for no reusable content. Since Scott asks only for "a small amount of the terminology of category theory", the ~50-line self-contained class below supplies exactly that vocabulary while keeping every proof constructive and choice-free. The Mathlib ``Category`` is therefore *usable* but counterproductive

```
* for
this development, and is deliberately not used.

# Lecture VI -- Proposition 6.6 (Scott 1981, PRG-19): initial algebras are uniquely isomorphic

**Proposition 6.6** Any two initial  $T$ -algebras are uniquely isomorphic.

The proof is the standard diagram chase. If  $A$  and  $B$  are both initial, initiality gives
unique
homomorphisms  $f : A \rightarrow B$  and  $g : B \rightarrow A$ . Their composites  $g \circ f : A \rightarrow A$  and
 $f \circ g : B \rightarrow B$  are
homomorphisms, and by uniqueness of homomorphisms out of an initial algebra they must equal the
identity homomorphisms. Hence the underlying morphisms of  $f$  and  $g$  are mutually inverse,
giving an
isomorphism  $A.\text{carrier} \simeq B.\text{carrier}$ . The isomorphism is unique in that the homomorphism  $A
\rightarrow B$ 
realising it is the only one (iso_hom_unique).

# Lecture VI -- Proposition 6.7 (Scott 1981, PRG-19): Lambek's lemma

**Proposition 6.7.** If  $i : T(D) \rightarrow D$  is an initial  $T$ -algebra, then so is  $T(i) : T(T(D)) \rightarrow T(D)$ 
and  $i$  is the isomorphism from  $T(D)$  to  $D$ .

We formalise the second (and decisive) half: the structure map of an initial algebra is an
isomorphism. Writing  $A = (D, i)$ , the functor turns  $i$  into a new algebra  $(T(D), T(i))$  (tStr),
and  $i$  itself is a homomorphism  $(T(D), T(i)) \rightarrow (D, i)$  (strHom). Initiality supplies a
homomorphism  $j : (D, i) \rightarrow (T(D), T(i))$ , and the composite  $i \circ j : (D, i) \rightarrow (D, i)$ 
must be the
identity (str_comp_desc). Functoriality then gives  $T(i) \circ j = T(i \circ j) = I$ ,
and the
homomorphism square for  $j$  yields  $j \circ i = I$ . Hence  $i$  and  $j$  are mutually inverse:  $i$ 
is an
isomorphism (lambek).

This is exactly Scott's remark that "if we are going to have initial algebras at all we have to
satisfy the domain equation  $D \cong T(D)$ ".

# Lecture VI -- Definition 6.8 (Scott 1981, PRG-19): functors *continuous on maps*

> **DEFINITION 6.8.** On the category of domains and strict approximable maps a functor `T` is
> *continuous on maps* if for any systems `D` and `E` the induced mapping
> `fun f. T(f) : (D -> False E) -> (T(D) -> False T(E))` is approximable.

This is the continuity condition that powers Theorem 6.9 (existence of homomorphisms out of a
fixed
point `D ~= T(D)`): the homomorphism equation `h = k comp T(h) comp j` is a fixed-point
equation for the map
`fun h. k comp T(h) comp j`, and it has a solution precisely because `fun h. T(h)` -- hence
the whole operator -- is
itself an approximable (so continuous) self-map of a function-space domain.

```

What the formalization uses

```

* **The category and the functor.** `T` is an `Endofunctor DomainObj` (Definition 6.3): an
  action
  `T.obj` on domains and `T.map` on the morphisms (here approximable maps, Theorem 2.5 laws).
* **The strict function space `(D → False E)`.** This is exactly Scott's domain on the left
  of the
  induced map. The project already constructs it in `Exercise510.lean`: `strictFun D E` is the
  neighbourhood system whose elements are the strict approximable maps (`IsStrict f`, i.e.
  `f(False) = False`), with the representation `strictFunEquiv : |D → False E| →o StrictMap D
  E` mirroring
  Theorem 3.10. So this Definition is stated over Scott's strict maps verbatim, not the
  full
  function space.
* "is approximable". In this framework a function between domains is approximable exactly
  when
  it is the elementwise action (`toElementMap`) of an approximable map (Proposition 2.2 /
  Theorem
  3.10). So `fun f. T(f)` being approximable is rendered as the existence of a witnessing
  `? : (D → False E) → (T(D) → False T(E))` (an `ApproximableMap` between the two strict
  function-space
  domains) whose action reproduces `T` on the underlying maps -- transported across the
  representation `strictFunEquiv` via `toStrictFilter`/`toStrictMap`.

```

Because the witnessing equation reads off the underlying map of a `StrictMap`, it automatically forces
`T.map f` to be strict whenever `f` is (lemma `ContinuousOnMaps.isStrict\_map`): a `T`
continuous on
maps does restrict to Scott's subcategory of strict maps, as required.

A design note on the category (strict maps vs. all maps)

Scott states 6.8 on the category of domains and *strict* maps, whereas the project's abstract
spine
(Definitions 6.3–6.7) is built on the all-maps `DomainObj` category (its `Hom` is the full
`ApproximableMap`). We bridge the two faithfully without introducing a second, strict-map
category
abstraction: the functor here is still `T : Endofunctor DomainObj` (acting on *all* maps), but
the
continuity condition is stated over the *strict* function spaces `(D → False E)`, and
strictness-preservation
is then *derived* (`ContinuousOnMaps.isStrict\_map`) rather than assumed. So `T` lives on the
all-maps
category, yet "continuous on maps" pins down exactly the behaviour Scott asks for on the strict
subcategory -- keeping Definition 6.8 coherent with the rest of the Lecture VI spine while
remaining
literally about Scott's strict maps.

The identity functor is continuous on maps (`continuousOnMaps\_id`), witnessing non-vacuity; its
representing `?` is the identity on the function space. Everything here is *choice-free*
(`#print axioms subseq {propteq, Quot.sound}`).

# Lecture VI -- Theorem 6.9 (Scott 1981, PRG-19): homomorphisms out of a fixed point
```

```
> **THEOREM 6.9.** If the functor `T` is *continuous on maps* (Definition 6.8) and if `D`  $\approx$  `T`  
  `(D)`, so  
> in particular `D` is a `T`-algebra, then for any `T`-algebra `k : T(E) -> E` there is a  
  homomorphism  
> `h : D -> E`.
```

Scott's proof. Let $i : T(D) \rightarrow D$ be the isomorphism making D a T -algebra and $j : D \rightarrow T(D)$ its inverse. A homomorphism $h : D \rightarrow E$ must satisfy $h \circ i = k \circ T(h)$, equivalently the **fixed-point equation**

$$h = k \circ T(h) \circ j.$$

The operator $\text{fun } h. k \circ T(h) \circ j$ on the **strict** function space $(D \rightarrow \text{False } E)$ is approximable: the inner $\text{fun } h. T(h)$ is approximable *precisely* by Definition 6.8 (`ContinuousOnMaps`), and post- and pre-composition with the fixed maps k , j is approximable too. Hence by the Lecture IV fixed-point theory (Theorem 4.1, `fixElement`) it has a least fixed point h , the desired homomorphism.

What the formalization does

We work over Scott's **strict** function space $(D \rightarrow \text{False } E) = \text{strictFun } D.\text{sys } E.\text{sys}$ (Exercise 5.10), exactly matching Definition 6.8.

****homOpComp**** -- the strict composite $g \mapsto k \circ g \circ j$ as a `StrictMap`.
 Strictness of the composite
 uses that j is strict (any isomorphism of domains preserves `False`, `isStrict_of_comp_eq_id`) and k
 is strict (a morphism of Scott's **strict** category; carried as a hypothesis), so $T(h) \circ j$ and then
 $k \circ T(h) \circ j$ stay strict.
****homOp**** -- the post/pre-composition map $(T(D) \rightarrow \text{False } T(E)) \rightarrow (D \rightarrow \text{False } E)$, $g \mapsto k \circ g \circ j$, built by
 Exercise 2.8's `ofMono`. Its decisive **action lemma** `homOp_apply_filter` says
 $\text{homOp}(f\text{-hat}) = (k \circ f \circ j)^\sim$ for every strict f ; it is proved by reducing (through the strict representation `strictFunEquiv`) to single step neighbourhoods $[X, Z]$, where the "finite factoring"
 is just $N := [Y_1, Y_2]$.
* The operator is $\text{Op} = \text{homOp} \circ ?$, where $?$ is Definition 6.8's witness that $\text{fun } f. T(f)$ is
 approximable. Its `fixElement` represents the strict map h ; the fixed-point equation (`toElementMap_fixElement`) unwinds -- via $?$'s defining property and `homOp_apply_filter` -- to
 $h = k \circ T(h) \circ j$, which rearranges (using $j \circ i = I$) to the homomorphism square
 $h \circ i = k \circ T(h)$.

```

The conclusion is `Nonempty {g : AlgHom <D, i> B // IsStrict g.hom}` -- Scott's *existence*
statement,
recording that the homomorphism is itself a strict map (it is `toStrictMap` of the fixed point)
, which
the uniqueness half of Theorem 6.14 consumes. Extracting `?` from the `Prop`-valued `
ContinuousOnMaps`
is done by `Exists.elim` while proving a `Prop`, so it stays **choice-free**
(`#print axioms subseq {propext, Quot.sound}`).

# Lecture VI -- Definition 6.10 (Scott 1981, PRG-19): the subsystem relation `D ? E`

To explain why the minimal solutions of a domain equation exist, Scott introduces a notion of
"subdomain". The functors `T` he has in mind are not merely continuous on maps (Definition 6.8)
but
also possess continuity properties on domains, and those are phrased in terms of this
relation.

**Definition 6.10.** For two neighbourhood systems `D` and `E` over the same set of tokens `
Delta`,
we write `D ? E` to mean that
* `D` subseqeq `E` (every neighbourhood of `D` is a neighbourhood of `E`), and
* whenever `X, Y` in `D` and `X I Y` in `E`, then `X I Y` in `D`.

The second clause is the crucial one: it says the notion of consistency in `D` is the same
as

```

in E . A subdomain is a smaller family of neighbourhoods, but it must agree with E about which pairs are consistent.

This module formalizes the relation together with the elementary facts Scott records in the prose:

```
* it is reflexive (`Subsystem.refl`) and transitive (`Subsystem.trans`);
* it is antisymmetric (`Subsystem.antisymm`): `D ? E` and `E ? D` force `D = E`;
* **Scott's remark.** If `D_0 ? E` and `D_1 ? E`, then `D_0 ? D_1 <=> D_0 subseq D_1`
  (`Subsystem.subsystem_iff_subset_of_common`) -- once both sit inside a common `E`, the
  subdomain relation collapses to plain inclusion of neighbourhood families.
```

Everything here is at the Prop level and **choice-free** (`#print axioms subseq {propt, Quot.sound}`).

Propositions 6.11 (the subsystems of E form a domain) and 6.12 (a $D ? E$ yields a projection pair i, j) build on this relation and are formalized separately.

```

# Lecture VI -- Proposition 6.11 (Scott 1981, PRG-19): the subsystems of `E` form a domain

**Proposition 6.11.** For a given neighbourhood system `E`, the set of subsystems

`{D ? D ? E}`

forms a domain in its own right.

Scott derives this as a one-line corollary of the remark preceding it: *the union of a directed
family of subdomains of `E` is again a subdomain*. We make this precise using the project's
**abstract representation theorem** (Exercise 2.22, `Exercise222.reprIso`): a family `C` of
sets
that is closed under (i) non-empty intersection and (ii) directed union is order-isomorphic to
a
domain `|reprSystem C|` -- exactly the route used for "the open sets form a domain" (Exercise
3.25)
and "the function space is a domain" (Exercise 3.27).

The faithful translation runs as follows. A subsystem `D ? E` is, by `NeighborhoodSystem.ext`
and
the standing `D.master = E.master`, completely determined by its **family of neighbourhoods**
`{X ? D.mem X}`. So we represent the poset `( {D ? D ? E}, ? )` by the family

`subFam E = { {X ? D.mem X} ? D ? E } subseq ?(?(Delta))`,

ordered by `subseq`. By Scott's remark (`Subsystem.subsystem_iff_subset_of_common`) the
subdomain
relation `?` between two subsystems of `E` is just inclusion of their neighbourhood families,
so
`( {D ? D ? E}, ? )` is isomorphic to `(subFam E, subseq)` (`subIso`). The two closure properties hold:

* **non-empty intersections** (`subFam_sInter_mem`): the intersection of a non-empty family of
subdomains is the subdomain `interSys` whose neighbourhoods are the common neighbourhoods;
* **directed unions** (`subFam_sUnion_mem`): the union of a directed family of subdomains is
the
subdomain `unionSys` (Scott's remark) -- directedness is used exactly to verify closure under
consistent intersection.

The capstone `subsystemReprIso : {D ? D ? E} ?o |reprSystem (subFam E) ...|` composes `subIso`
with
`Exercise222.reprIso`, witnessing that the subsystems of `E` *are* (isomorphic to) a domain.

**Axioms.** The combinatorial heart -- `subFam` and its closure under intersection/union, the
subsystem constructions `interSys`/`unionSys`, and `subIso` -- is **choice-free**
(`#print axioms subseq {proptext, Quot.sound}`). The final `subsystemReprIso` inherits `
Classical.choice`
solely through Exercise 2.22's representation isomorphism (the "for set theorists" exercise,
which
picks witnesses of non-emptiness and uses finite-set induction), exactly as Exercise 3.27 does.

# Lecture VI -- Proposition 6.12 (Scott 1981, PRG-19): a subdomain yields a projection pair

**Proposition 6.12.** If `D ? E`, then there exists a *projection pair* of approximable
mappings

`i : D -> E` and `j : E -> D`

with `j ∘ i = I_D` and `i ∘ j ⊆ I_E`, determined as element-wise functions
by

`i(x) = {Y in E ? exists X in x, X ⊆ Y}` and `j(y) = y ∩ D`.

Scott leaves the proof "for the exercises". We give it directly at the level of the
neighbourhood

```

relations (Definition 2.1), which keeps everything **choice-free**.

* The injection ``i`` (``Subsystem.inj``) is the relation ``X i Y <-> X in D /\ Y in E /\ X subseq Y`` -- it sends a ``D``-neighbourhood to all the ``E``-neighbourhoods it refines.
 * The projection ``j`` (``Subsystem.proj``) is the relation ``Y j X <-> Y in E /\ X in D /\ Y subseq X`` -- it intersects an ``E``-element with ``D``.

The two laws are then short relational calculations:

* ``Subsystem.proj_comp_inj : j comp i = I_D``. Both round trips factor as ``X subseq Y subseq Z``, giving exactly the identity relation ``X subseq Z`` on ``D``. (Proved with the **choice-free** relational extensionality ``ApproximableMap.ext``.)
 * ``Subsystem.inj_comp_proj_le : i comp j subseq I_E``. A round trip ``Y subseq X subseq Y`` through a common ``D``-neighbourhood ``X`` is in particular ``Y subseq Y`` on ``E`` -- but not conversely, so this direction is only an inclusion. The crucial clause of ``D ? E`` (consistency inherited from ``E``) is what makes ``j``'s output-intersection law hold (``inter_right``).

The element-wise descriptions Scott records are ``Subsystem.toElementMap_inj`` and ``Subsystem.toElementMap_proj``.

Everything here is **choice-free** (``#print axioms subseq {prope, Quot.sound}``).

# Lecture VI -- Definition 6.13 (Scott 1981, PRG-19): functors *monotone / continuous on
domains*

> **DEFINITION 6.13.** A functor `T` is *monotone on domains* iff whenever `D ? E`, then not
only do
> we have `T(D) ? T(E)` but the projection pair `i, j` of 6.12 is mapped to the same kind of
> projection pair `T(i), T(j)`. A monotone functor is *continuous on domains* iff whenever `E`
is a
> domain, then the mapping `fun D. T(D) : {D ? D ? E} -> {D' ? D' ? T(E)}` is approximable.

```

This is the second of Scott's two continuity conditions on a functor (the first being Definition 6.8, *continuous on maps*). Together with a generating set Γ they power the existence Theorem 6.14 (initial T -algebras as iterated-functor colimits $T = \varinjlim T(\Gamma)$).

What the formalization uses

* **The functor.** T is an $\text{Endofunctor DomainObj}$ (Definition 6.3), acting on objects ($T.\text{obj}$) and on the approximable maps between them ($T.\text{map}$).

* **The subdomain relation $\preceq$.\text{Subsystem}), between two systems over the *same* token type, with the projection pair $i = \text{Subsystem.inj}$, $j = \text{Subsystem.proj}$ of Proposition 6.12.

* **The domain of subsystems $\{D \preceq D' \preceq E\}$.\{D \text{ // } D' \preceq E\} and the directed-union sups are the union subsystems unionSys .

The carrier-type subtlety, and how it is handled
