/-! ### The closed form: `YseqCode` recovers the "+"-piece of the atom recursion

Mirrors `Theorem88.lean`'s `split_fst_eq_inter_Yseq`: the "+"-branch chosen at depth `n` by the
atom recursion is exactly the intersection of the depth-`n` atom with `YseqCode`. Pairwise
disjointness (`atomUCode_disjoint`) is what rules out any *other* atom leaking a point into
`UX (YseqCode P n)` that isn't already forced into this one. -/

# Theorem 8.8(b)(vii)(3) -- a genuinely code-driven subsystem `D`

`Theorem88d.lean` (Part 7) builds a fully `Nat.Primrec` back-and-forth recursion -- `atomUCode`
`/
`YseqCode` -- tracking `U`-codes natively, and proves the two halves of Scott's matching
invariant
at the code level: validity (`atomUCode_mem`, free) and the emptiness-match
(`genAtom_Yc_empty_iff`, where `Yc P n := UX (YseqCode P n)`). This file finishes the job Scott
's
own Theorem 8.8(a)/(b) Part 6 (`Theorem88a.lean`/`Theorem88c.lean`) already did for the *
classical*
`Yidx (e P)` -- but for `Yc P` instead, which is genuinely code-driven: unlike `Yidx`,
whose
*value* is whatever `Classical.choice` happened to pick, `Yc P n = UX (YseqCode P n)` is *
literally*
`UX` applied to a `Nat.Primrec` function of `n` and `P`'s own deciders.

## Plan

* Port the finite-constraint transfer lemmas (`Theorem88.lean`'s `transfer_dir`/`
transfer_empty_iff`
/`transfer_subset_iff`/`transfer_inter_eq_iff`) to the pair `(idxSet (e P), Set.univ)` vs.
`(Yc P, U.master)`, using `genAtom_Yc_empty_iff` (plus `encodeBits`, realizing any finite
prefix of

```

```

an arbitrary `? : Nat -> Bool` as some `deltaOf k`) as the emptiness-matching core, in place
of
`atomU_invariant`/`atomU_eq_genAtom`.
* Assemble `D'' := DprimeUCode`, `D ~=? D''`, `D'' ? U` -- mirroring `Theorem88a.lean`'s
`DprimeU`/`domainIso`/`DprimeU_subsystem` verbatim, with `Yidx (e P) |-> Yc P` and the
transfer
lemmas above in place of `Theorem88.lean`'s generic ones.
* Build `ComputablePresentation D''` with `X n := Yc P n`, master index `0` -- mirroring
`Theorem88c.lean`'s `DprimeUPresentation`, reusing `idxSet_inter_eq_iff_DAtom`/
`DAtom_pair_recDecidable`/`(P0 P).incl_computable`/`(P0 P).cons_computable`/`(P0 P).inter`
unchanged (the *index relations* were already decidable; only the *carrier family* changes).

/--! ## Realizing any finite `?`-prefix as `deltaOf k` for some `k`

`genAtom_Yc_empty_iff` only relates `genAtom` at sign sequences of the special form `deltaOf k`
`.
The general finite-constraint transfer lemma (`transfer_dir`, below) needs the emptiness match
for
*every* `? : Nat -> Bool`. Since `genAtom Z M ? n` only inspects `? 0, ..., ? (n - 1)` (`
genAtom_congr`),
it suffices to realize any finite prefix of `?` as `deltaOf k` for a suitable `k < 2 ^ n`. -/

/-- **`?'s length-`n` bit-encoding**:: the natural number `< 2 ^ n` agreeing with `?' on every
bit
below `n`. -/

# Theorem 8.8(b)(vii)(4) -- the projection pair `D' ? U` is computable

`Theorem88e.lean` (Part 7's third sub-part) assembled `D' := DprimeUCode P`, `D ~ = ? D'`,
and
`D' ? U`, with `D'`'s own `ComputablePresentation` (`DprimeUCodePresentation`, master index
`0`,
`X n := Yc P n = UX (YseqCode P n)`). This file supplies the actual headline claim of Theorem
8.8(b)(vii): the projection pair `i := (D' ? U).inj`/`j := (D' ? U).proj` (Proposition 6.12)
is
**computable** (Definition 7.2, `IsComputableMap`) relative to `DprimeUCodePresentation`/
`UComputablePresentation`.

## Why this is now easy

Both relations unfold (`Subsystem.inj_rel`/`Subsystem.proj_rel`) to a `mem`-clause on each side
*plus* a raw subset test -- and every `mem`-clause is automatically true once both sides are
read off
their own presentations (`<n, rfl>` for `D'`, `U_mem_UX` for `U`), so `i`/`j`'s relations
reduce to
exactly

* `i`: `Yc P n subseq UX m`, i.e. `UX (YseqCode P n) subseq UX m`;
* `j`: `UX m subseq Yc P n`, i.e. `UX m subseq UX (YseqCode P n)`;

both instances of the single **generic** fact `X_n subseq X?` is recursively decidable for
*any*
`ComputablePresentation` (`ComputablePresentation.incl_computable`, Definition 7.1), here
applied to
`UComputablePresentation` and reindexed along the `Nat.Primrec` function `YseqCode P`
(`primrec_YseqCode`, Theorem 8.8(b)(vii)(2)) in one argument. No new `Nat.Primrec` machinery,
no new
decidability core -- the entire content is packaging two reindexings of `incl_computable`,
decidable
hence r.e. (`RecDecidable.re`).

# Theorem 8.8(b)(viii) -- final assembly

`Theorem88e.lean` (Part 7(3)) built `D' := DprimeUCode P`, the isomorphism `D ~=? D'`
(`isomorphic_DprimeUCode`), the subsystem relation `D' ? U` (`DprimeUCode_subsystem`), and `D
's
own `ComputablePresentation` (`DprimeUCodePresentation`); `Theorem88f.lean` (Part 7(4)) showed
the
projection pair witnessing `D' ? U` (Proposition 6.12's `inj`/`proj`) is computable relative
to
`DprimeUCodePresentation`/`UComputablePresentation`
(`DprimeUCode_projectionPair_isComputable`). This file packages all of it into the single
headline
statement of Theorem 8.8(b): if `D` is effectively given, the projection pair witnessing
`D ? U` (Theorem 8.8(a)) can be taken computable.

No new mathematical content -- every ingredient already exists; this is exactly `theorem_8_8_a
's
statement (`Theorem88a.lean`) with `D` replaced by a presented `D` and the projection pair
additionally asserted computable.
-/

# Theorem 8.8(c), Part 1 of 6 -- the diagonal fixed-point predicate is recursively enumerable
```

```
Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19, Theorem 8.8(c):
```

```
the converse direction to Theorem 8.8(b) -- a computable, finitary projection `a` of `??` yields an
effectively given domain `{Y in ?? Y a Y} ??` (Theorem 8.5's `fixedNbhd a`, already known
to be a
subsystem for *any* approximable map `a`).
```

```
## This file
```

```
The naive plan ("`a`'s graph r.e. + `??`-equality decidable ? `{Y in ?? Y a Y}` r.e. ?
effectively
```

```
given") glosses over a real gap: `X_n a X_n` being merely **r.e.**, not decidable, means the
raw index
```

```
set `S := {n ? X_n a X_n}` cannot be *filtered* directly into a `ComputablePresentation`'s
enumeration
```

```
-- `interEq_computable`/`cons_computable` need genuinely decidable relations and a *primitive
recursive* `.inter`. The 6-part plan (mirroring Theorem 8.8(b)'s style) starts here, with Part
1: pin
```

```
down `S`'s defining predicate (`DiagFixed`) and extract, from `a`'s computability, the
underlying
```

```
recursively **decidable** witness relation that Parts 2-4 will gate a primitive-recursive fold
on.
```

```
`DiagFixed P a n := a.rel (P.X n) (P.X n)` is exactly (`diagFixed_iff_fixedNbhd_mem`) the
condition
```

```
`(fixedNbhd a).mem (P.X n)`, i.e. `P.X n` (already a `V`-neighbourhood) is a neighbourhood of
Theorem
```

```
8.5's subsystem `fixedNbhd a = {X in V ? X a X}`.
```

```
`diagFixed_isREPred` restricts `IsComputableMap P P a`'s two-variable r.e. relation `X_n a X`'
to the
```

```
diagonal `n = m` via `REPred.comp` against the primitive-recursive pairing `n |-> <n, n>` --
no new
```

```
mathematical content, purely a reindexing of Definition 7.2's hypothesis.
```

```
`diagFixed_exists_qChar` then unfolds `REPred`'s own definition (`p n <-> exists i, q <i,n>`
with `q`
```

```
recursively decidable via a `{0,1}`-valued primitive-recursive characteristic `qChar`) to
expose that
```

```
characteristic function directly: `DiagFixed P a n <-> exists i, qChar <i,n> = 1`. This `
qChar` is exactly
```

```
what Theorem 8.8(c) Parts 2-4 (the gated fold `myFoldCode`, its invariant, and the `D`-side
deciders)
```

```
will consume -- no unbounded search is *primitive* recursive, but a fold that only ever *tests*
an
```

```
already-produced index against `qChar` (rather than searching for a fresh witness) is.
```

```
All of this is stated for a general neighbourhood system `V` and computable presentation `P` (
not
```

```
just `??`), since none of the mathematics is specific to the universal domain; Theorem 8.8(c)
```

```

    itself
will specialize `V := ?`, `P := UComputablePresentation`. Everything here is **choice-free**
(`subsetq {propext, Quot.sound}`): built only from `Definition72.lean`'s choice-free `
    IsComputableMap` and
`Recursive.lean`'s choice-free `REPred`/`RecDecidable` closure lemmas.

# Theorem 8.8(c), Part 2 of 6 -- a `qChar`-gated primitive-recursive fold landing back in `
  DiagFixed`

Following Theorem 8.8(c)'s 6-part plan (`arxiv.md`): Part 1 (`Theorem88h.lean`) produced, from
  a
computable map `a`, a `{0,1}`-valued primitive-recursive `qChar` with `DiagFixed P a n <->
  exists i,
qChar<i,n> = 1`. This file builds the fold that will let Part 3 enumerate `fixedNbhd a`: a
primitive-recursive list-fold whose accumulator is always a raw index already satisfying
`DiagFixed`, no matter what list it is fed -- so no unbounded search is ever needed once `qChar
  (an
r.e., not decidable, fact) has been supplied per list entry as a checked witness pair.

## Design (mirroring `DAtomDecidable.lean`'s `meetStep`/`meetFold`/`meetFoldCode`, simplified)

Each list entry `e` codes a pair `i, n = Nat.pair i n`: `n` is a candidate raw index and `i`
  is a
claimed `qChar`-witness for it. One step of the fold (`myStep`), given the current
  accumulator `r`
(already known -- by the invariant -- to satisfy `DiagFixed`) and the next entry `e`:

* checks `qChar e = 1` (this literally checks `qChar (Nat.pair i n) = 1`, so -- reading `hqChar
  backwards -- witnesses `DiagFixed P a n` for `n := e.unpair.2`, no unbounded search needed
  since the
  witness `i` was given, not searched for);
* checks the `V`-consistency decider `cons (Nat.pair r n) = 1` (i.e. `exists k, X k subseteq
  X? I X_n`);
* if both succeed, advances the accumulator to `P.inter r n` (which lands back in `
  DiagFixed` by
  `fixedNbhd_subsystem`'s `inter_closed`, since `X? I X_n` is then both a genuine `V`-
  neighbourhood
  and an intersection of two `fixedNbhd a`-neighbourhoods);
* otherwise no-ops, leaving the accumulator at `r` unchanged (unlike `meetStep`'s permanent
  "not ok" freeze -- here an invalid or inconsistent entry is simply skipped, since we are
  not
  trying to prove anything about the particular list fed in, only that whatever comes out the
  other
  end is still `DiagFixed`).

The base case is `P.masterIdx`, always `DiagFixed` since `a.master_rel : a.rel V.master V.
  master`
transported along `P.masterIdx_spec`. No `(ok, idx)` pair is needed in the accumulator (unlike
`meetStep`) precisely because a bad entry is dropped rather than remembered.

`myStepCode`/`myFoldCode` package `myStep`/`myFold` at the `Nat.Primrec` level via the existing
`foldCode` combinator (`Recursive.lean`); `Nat.Primrec` is immediate from `primrec_foldCode`
  given
`qChar`, `cons`, and `P.inter` are all primitive recursive. The headline result,
`diagFixed_myFoldCode`, is the invariant "`DiagFixed P a (myFoldCode qChar cons c)` for every
  list-code
`c`" -- Part 3 will show this enumeration is onto `fixedNbhd a`.

```

```

Everything here is choice-free (`subseq {propext, Quot.sound}`), built purely from `Recursive.lean`'s
choice-free `foldCode`/`selectFn`/`isOne` machinery and `Theorem85.lean`'s choice-free
`fixedNbhd_subsystem`.

# Theorem 8.8(c), Part 3 of 6 -- the induced enumeration covers `fixedNbhd a`

Following Theorem 8.8(c)'s 6-part plan (`arxiv.md`): Part 2 (`Theorem88i.lean`) built a
`qChar`-gated primitive-recursive fold `myFoldCode` whose output, for every list-code `c`, is
a

```

```

raw index `myFoldCode qChar cons c` satisfying `DiagFixed P a` (Part 1's r.e. diagonal
  predicate,
  <-> (fixedNbhd a).mem (P.X *)). This file packages that enumeration and shows it is exactly
    onto
  `fixedNbhd a`.

`D_X qChar cons c := P.X (myFoldCode qChar cons c)` :

* **`D_X_mem`** -- every `D_X qChar cons c` is a `fixedNbhd a`-neighbourhood: immediate from
  Part 2's
  invariant `diagFixed_myFoldCode` via `diagFixed_iff_fixedNbhd_mem`.
* **`D_X_of_diagFixed`** -- the reusable core of the surjectivity argument: for *any* raw `V`-
  index
  `m` already known to be `DiagFixed` (not necessarily `myFoldCode`'s own output), some `D_X`
  value
  hits `P.X m` on the nose. Part 1's `hqChar` extracts a witness `i` with `qChar <i, m> = 1`.
  Feeding the **singleton list `[<i, m>]`** (encoded via `encodeList`) into the fold performs
  exactly one step from `P.masterIdx`: the `qChar`-gate passes by construction, and the
  `V`-consistency gate passes because `P.X m subseq V.master = P.X P.masterIdx` (`V.
  sub_master`) makes
  `P.masterIdx`/`m` trivially consistent via the witness `m` itself (`P.X m subseq P.X P.
  masterIdx I
  P.X m`, in fact equality). The fold therefore advances to `P.inter P.masterIdx m`, and
  `P.inter_spec` gives `P.X (P.inter P.masterIdx m) = V.master I P.X m = P.X m`.
* **`D_X_surj`** -- every `fixedNbhd a`-neighbourhood `Y` is hit by some `D_X qChar cons c` :
  `P.surj` produces a raw `V`-index `n_0` with `P.X n_0 = Y`, which is `DiagFixed` since `Y` is
  `a`-fixed, so `D_X_of_diagFixed` finishes it. (This reduction is also exactly what Theorem
  8.8(c) Part 4 needs for its `cons_computable` direction `?`, applied instead to `m := P.inter
  n_1 n_2` -- hence factoring `D_X_of_diagFixed` out here rather than inlining it.)

Everything here is **choice-free** (` subseq {propt, Quot.sound}`), built purely from `
  Theorem88h.lean`/
`Theorem88i.lean`'s choice-free apparatus plus `Recursive.lean`'s choice-free `encodeList`/
`decodeList` round-trip.

# Theorem 8.8(c), Part 4 of 6 -- `D_X`'s `interEq`/`cons` relations are recursively decidable

Following Theorem 8.8(c)'s 6-part plan (`arxiv.md`): Part 3 (`Theorem88j.lean`) built the
enumeration `D_X qChar cons c := P.X (myFoldCode qChar cons c)` and showed it is onto `
fixedNbhd
a`. This file proves the two relations Definition 7.1 actually needs are recursively decidable
*on the list-codes* `c` (not on the underlying `V`-indices, which are already handled by `P`).

## `interEq_computable` -- free

`D_X c_1 I D_X c_2 = D_X c_3` unfolds *literally* to `P.X n_1 I P.X n_2 = P.X n_3` for `n_i
:= myFoldCode
qChar cons c_i`, so this is exactly `P.interEq_computable` reindexed along the (primitive-
recursive,
Part 2's `primrec_myFoldCode`) triple `(c_1, c_2, c_3) |-> (myFoldCode c_1, myFoldCode c_2,
myFoldCode c_3)`.
No `a`/`DiagFixed` apparatus is needed at all.

## `cons_computable` -- the one genuine lemma

`D_X_cons_iff` is the mathematical content of this part: `D`-consistency of two list-codes,
`exists k, D_X k subseq D_X c_1 I D_X c_2`, is **equivalent** to plain `V`-consistency
of the underlying raw
indices, `exists k', P.X k' subseq P.X n_1 I P.X n_2`:

* `?` is immediate: any `D`-side witness `D_X k = P.X (myFoldCode qChar cons k)` is *already* a
`V`-side witness, since `D_X`'s codomain is literally `P.X` of some raw index -- no separate
"is this really `V`-consistent" check is needed.
* `?` needs Theorem 8.8(c) Part 3's `D_X_of_diagFixed`: given a `V`-consistency witness `k`,
`P.inter_spec` gives `P.X (P.inter n_1 n_2) = P.X n_1 I P.X n_2`; since `n_1`, `n_2` are
both
`DiagFixed` (Part 2's `diagFixed_myFoldCode`, as they are `myFoldCode`-outputs), so is their
meet (`fixedNbhd_subsystem a`'s `inter_closed`, transported along the equation above), and
`D_X_of_diagFixed` then produces the `D`-side witness code directly.

Once this equivalence is in hand, `cons_computable` is `P.cons_computable` composed with the
same
primitive-recursive `myFoldCode`-pair reindex used for `interEq_computable`.

Everything here is **choice-free** (`subseq {propeq, Quot.sound}`), built purely from `
Theorem88h.lean`-
`Theorem88j.lean`'s choice-free apparatus plus `Definition71.lean`'s choice-free `RecDecidable`
closure lemmas (`comp`/`of_iff`).

# Theorem 8.8(c), Part 5 of 6 -- a primitive-recursive `D_X` and its `inter_spec`

Following Theorem 8.8(c)'s 6-part plan (arxiv.md): Parts 1-4 built the enumeration D_X qChar
cons c := P.X (myFoldCode qChar cons c), showed it is onto fixedNbhd a, and showed its
interEq/cons relations are recursively decidable. This file supplies the last data field
ComputablePresentation needs: a primitive-recursive D_inter : Nat -> Nat -> Nat with
D_X (D_inter c_1
c_2) = D_X c_1 I D_X c_2 whenever the two are D-consistent.

## The construction: D_inter c_1 c_2 := appendListCode c_1 c_2

Concatenating the two list-codes (Recursive.lean's Exercise 7.22 appendListCode/primrec_appendListCode/appendListCode_eq, reused outright) is exactly right because
myFoldCode is a *left* fold from P.masterIdx, so folding the concatenated list decomposes
(List.foldl_append) as folding c_2's list *starting from* myFoldCode c_1 instead of from
P.masterIdx:

...
myFoldCode (appendListCode c_1 c_2) = (decodeList c_2).foldl myStep (myFoldCode c_1)
...

## The one genuine lemma: refolding from a smaller start intersects

myFoldl_inter_of_le is the mathematical content: for a list l, refolding it from a
DiagFixed-irrelevant starting point n subseq r (in P.X) reproduces P.X n I P.X (
fold from r),
**provided** the two are already known V-consistent at the *end* of the fold. The key
subtlety
is that myStep's gate (cons (Nat.pair r e.unpair.2) = 1) is *accumulator-dependent*, so
refolding the same list from a smaller start could in principle skip steps the original fold
took.
The induction shows this never happens: any step that *succeeds* from r also succeeds from n
,
because the global witness (consistency of n with the *final* fold value) is inherited by
every
intermediate accumulator via the fold's monotone-shrinking property (myFoldl_subset); and any

```

step that **fails** from ``r`` also fails from ``n``, since success from the (`subseq -smaller`) ``n`` would imply success from ``r`` too (monotonicity of ``cons``'s witness in the `subseq` direction).

Given this, Part 5's ``D_X_inter_spec`` is immediate: unfold both sides via ``appendListCode_eq`/`List.foldl_append``, apply ``myFoldl_inter_of_le`` with ``n := myFoldCode c_1``, ``r := P.masterIdx`` (using ``V.sub_master`` for ``n subseq r``), and the hypothesis (already ``V``-side, since ``D_X``'s codomain **is** ``P.X`` of some raw index -- no reindexing needed, unlike Part 4's ``cons_iff``).

Everything here is ***choice-free*** (``subseq {propext, Quot.sound}``): ``Recursive.lean``'s ``list_eq_of_getD`/`appendListTabFn_eq`/`primrec_appendListTabFn`/`primrec_appendListCode`` were tightened in this session (dropping a stray ``by_contra`/lemma-set `simp`` that pulled in ``Classical.choice``) to be choice-free outright, so no new taint is introduced here.

# Theorem 8.8(c), Part 6 of 6 -- final assembly

Following Theorem 8.8(c)'s 6-part plan (`arxiv.md`): Parts 1-5 (`Theorem88h.lean` - `Theorem88l.lean`)
built, relative to an arbitrary `qChar`/`cons` : Nat -> Nat satisfying the two extracted
hypotheses
`hqChar`/`hcons`, an enumeration `D_X qChar cons : Nat -> Set a` that is onto `fixedNbhd a`
(`D_X_mem`/`D_X_surj`), has recursively decidable `interEq`/`cons` relations
(`D_X_interEq_computable`/`D_X_cons_computable`), and a primitive-recursive `inter`
(`D_inter`/`D_inter_primrec`/`D_X_inter_spec`). This file supplies the two missing concrete
witnesses (`qChar` from Part 1's `diagFixed_exists_qChar`, `cons` from `P.cons_computable`
itself)
and packages the result into a genuine `ComputablePresentation (fixedNbhd a)`, proving the
headline:

> **Theorem 8.8(c).** If `a : U -> U` is a computable, finitary projection, then
> `{Y in U ? Y a Y} = fixedNbhd a` is effectively given (and, by Theorem 8.5/8.6(a), a
> subsystem of
> `U`).

## Why the two witnesses cause no `Classical.choice`

Both `qChar` and `cons` are extracted from propositional existentials (`diagFixed_exists_qChar`,
`P.cons_computable` -- both `RecDecidable`-shaped `exists f, ...`) via plain `obtain`, which
is legitimate
choice-free `Exists`-elimination **because the target of `fixedNbhd_isEffectivelyGiven` is
itself a`
`Prop` ** (`NeighborhoodSystem.IsEffectivelyGiven = Nonempty (ComputablePresentation V)`, and
`Nonempty` is a `Prop`) -- eliminating a `Prop`-valued `Exists` into a `Prop`-valued goal never
needs
choice, only eliminating into `Type`/`Data` does. This mirrors the discipline already used
throughout Lecture VII/VIII (e.g. `Theorem88a.lean`'s `theorem_8_8_a`, also a bare `Nonempty`
statement). We therefore do **not** state a `def`-level "the" presentation; only the `Prop`-
level
existence statement.

## Assembly

`hqChar`/`hqCharp` come straight from `diagFixed_exists_qChar hcomp` (Part 1). `hcons`/`hconsp`
come
from unfolding `P.cons_computable : RecDecidable_2 (fun n m => exists k, X? subseq X_n I X
?)`, i.e. `exists f`,
```

Nat.Primrec f /\ forall t, (exists k,...) <-> f t = 1` -- reindexing the `forall t` at `t`
:= Nat.pair n m` and simplifying
`unpair\_pair` gives exactly the `hcons` shape every one of Parts 2-5's lemmas expects.

The `masterIdx := 0` field needs `D\_X qChar cons 0 = (fixedNbhd a).master = V.master`:
unfolding
`D\_X`/`myFoldCode\_eq` reduces `myFoldCode qChar cons 0` to `myFold qChar cons (decodeList 0) =
myFold qChar cons [] = P.masterIdx` (`decodeList_zero`/`myFold_nil`), and `P.masterIdx_spec`
finishes
it.

Everything here is **choice-free** (`subseq {propext, Quot.sound}`): the only `Exists`-
eliminations are
into a `Prop` goal (see above), and every other ingredient (Parts 1-5) was already audited
choice-free. The generic `fixedNbhd\_isEffectivelyGiven` audits exactly this way. **The**
specialization
`theorem\_8\_8\_c` itself audits `subseq {propext, Classical.choice, Quot.sound}` -- but
this is *not* new
taint introduced here: `U` (`Definition87.lean`) already audits with `Classical.choice` for a
documented upstream reason (Mathlib's `Rat` order instance path), and the two other `U`-
mentioning
headline theorems, `theorem\_8\_8\_a`/`theorem\_8\_8\_b`, audit identically (confirmed directly). Any
proof
term merely *stating* something about `ApproximableMap U U`/_ ? `U` inherits `U`'s own
footprint.

# Theorem 8.8(b), strengthened -- a direct computable projection pair `D <=> U`

`theorem_8_8_b` (`Theorem88g.lean`) gives, for an effectively given `D`, an isomorphic copy
`D' : NeighborhoodSystem ?` (`= DprimeUCode P`) with a literal subsystem relation `D' ? U`
    whose
Proposition 6.12 projection pair (`h.inj`/`h.proj`) is computable -- but it stops there,
    leaving
`D ~=? D'` a bare `Nonempty (OrderIso ...)` fact, with no computable projection pair `D <=>
    U` for `D`
*itself*. Definition 8.9 needs exactly that (fixed projection pairs `?+? -> ?`, `? x ? ->
    ?`,
`? -> ? -> ?` and back), so this file supplies it.

## Why the iso is computable after all

`Theorem 2.7` (`ApproximableMap.ofIso`, `Approximable.lean`) turns any order-isomorphism
`e : D.Element ?o D'.Element` into an approximable map, choice-free. Applied to `domainIsoCode
    P`
this gives `isoInj P : D -> D'`/`isoProj P : D' -> D` (`D' := DprimeUCode P`) with the
    projection-pair laws
as plain equalities (Theorem 2.7 + `ext_of_toElementMap`, mirroring `Exercise618.lean`'s
    `jmap_comp_imap`).

The point of this file is that `isoInj`/`isoProj` are also computable, because `
    domainIsoCode` is built
(`Theorem88e.lean`) to match `D`'s and `D'`'s raw indices literally along the primitive-
    recursive

```

involution ``eIdx P`` (``Theorem88b.lean``): unfolding ``ofIso`/`toDprimeUCode`/`toDCode`` and using the raw-index correspondence ``embed_eq_iff_raw_code`` (``e P i = e P j <-> Yc P i = Yc P j``) collapses both relations to a single reindexed ``incl_computable`` query --

```
* `isoInj_rel_iff_incl`: `(isoInj P).rel (P.X a) (Yc P b) <-> P.X a subseteq P.X (eIdx P b)
  `;
* `isoProj_rel_iff_incl`: `(isoProj P).rel (Yc P b) (P.X a) <-> Yc P b subseteq Yc P (eIdx P a)`
```

(using that ``n := b``, resp. ``m := eIdx P a``, is already the "same-index" witness the general existential ranges over -- no other witness can give a different answer, by ``embed_eq_iff_raw_code``).

Composing ``isoInj`/`isoProj`` with ``(DprimeUCode_subsystem P).inj`/`.proj`` (computable, ``Theorem88f.lean``) via ``comp_isComputable`` then gives the headline ``theorem_8_8_b_strong``: a **single** computable projection pair ``D <=> U``, no intermediate ``D'`` in sight.

The reasoning in this file is itself ***choice-free***: ``isoInj`/`isoProj`` are built relationally (``ofIso``), and all the analysis is ``Exists`-elimination` into ``Prop`` goals or plain rewriting.

But ``theorem_8_8_b_strong`` (like ``theorem_8_8_b`/`DprimeUCode_subsystem`/`YseqCode`` themselves) audits ``subseteq {propxt, Classical.choice, Quot.sound}`` -- this is ***inherited***, not new taint: ``U`` (``Definition87.lean``) already audits with ``Classical.choice`` (Mathlib's ``Rat`` order instance path), and everything downstream that mentions ``U`/`UComputablePresentation`` inherits it (confirmed directly: ``U_isEffectivelyGiven``, ``DprimeUCode_subsystem``, ``YseqCode`` all show the same footprint).

# Definition 8.9 (Scott 1981, PRG-19) -- the combinators `a+b`, `a x b`, `a -> b` on
projections of `?`

> **Definition 8.9.** Let the computable projection pairs `i_+ : ?+? -> ?` and `j_+ : ? ->
?+?` be
> fixed. Similarly choose `i_x`, `j_x` and `i_->`, `j_->` for `? x ?` and `? -> ?`. Define,
for all
> `a, b : ? -> ?`:
>
> `a + b = cond comp <which, i_+ comp in_0 comp a comp out_0, i_+ comp in_1 comp b comp out_1
>   comp j_+`;
> `a x b = i_x comp <a comp proj_0, b comp proj_1> comp j_x`;
> `a -> b = i_-> comp (fun f. b comp f comp a) comp j_->`.

## The six fixed maps

`?+?`, `? x ?`, `? -> ?` are each effectively given (Theorem 7.4/7.5 applied twice to `U`'s own
presentation), so `theorem_8_8_b_strong` (`Theorem88n.lean`) hands each of them a *computable*
projection pair into `U`. Scott's "let ... be fixed" is exactly a choice out of that (non-
unique)
existential -- extracted here via `Exists.choose`, the same way every other "fixed but
arbitrary
choice" in this development is handled (e.g. `U` itself, `Definition87.lean`). Since
`theorem_8_8_b_strong` already carries `U`'s own inherited `Classical.choice` footprint (see
`Theorem88n.lean`), this extraction adds no *marginal* taint.

## The three combinators

Built by direct transcription of Scott's formulas from existing combinators: `cond`/`whichMap`
(Exercise 3.26), `inMap_0/_1`/`outMap_0/_1` (Exercise 3.18/3.19), `paired`/`proj_0/_1` (Lecture
III,
`Product.lean`), and `curry`/`evalMap`/`prodMap` (`FunctionSpace.lean`, Exercise 3.19) for the
`fun f. b comp f comp a` clause: uncurried, `(f,x) |-> b(f(a(x)))` is
`b comp eval comp (id x ? a)`, so `fun f. b comp f comp a = curry (b comp eval comp (
id x ? a))`.

# Proposition 8.10 (Scott 1981, PRG-19) -- the combinators preserve projections

**Proposition 8.10 (first half).** If  $a, b : ? \rightarrow ?$  are projections, then so are  $a+b$ ,  $a \times b$ ,
and  $a \rightarrow b$ .

*Scott's proof.*  $a, b \sqsubseteq_{\text{sub}} I$  gives  $a+b \sqsubseteq_{\text{sub}} I+I = i_+ \text{ comp } j_+ \sqsubseteq_{\text{sub}} I$  (similarly
for  $a \times b$ ,  $a \rightarrow b$ );
 $a = a \text{ comp } a, b = b \text{ comp } b$  gives  $(a \times b) \text{ comp } (a \times b) = i_+ \times \text{ comp } \langle a \text{ comp } a \text{ comp } \text{proj}_0, b \text{ comp } b \text{ comp } \text{proj}_1 \rangle \text{ comp } j_+ \times = a \times b$  (similarly for  $a+$ ,
 $a \rightarrow b$ ).

## What is formalized in this file

Both halves of Proposition 8.10 -- IsRetraction and  $\leq \text{idMap } U$ -closure -- for all
three
combinators, i.e.  $\text{IsProjection } a \rightarrow \text{IsProjection } b \rightarrow \text{IsProjection } (a*b)$  for  $*$  in  $\{+, \times, \rightarrow\}$ .

*  $a \times b$  (cleanest).  $\text{prodComb } a \ b$  is literally  $i \text{Times} \cdot \text{comp } ((\text{prodMap } a \ b) \cdot \text{comp } j \text{Times})$ 
( $\text{prodMap } a \ b = \langle a \text{ comp } \text{proj}_0, b \text{ comp } \text{proj}_1 \rangle$  is exactly Exercise 3.19's product-functor
combinator,
unfolding  $\text{prodComb}$ 's definition,  $\text{rfl}$ ). Both closure facts reduce, at the element level,
to
 $\text{pair\_le\_pair\_iff} / \text{toElementMap\_prodMap} / \text{toElementMap\_mono}$  plus the two generic
projection-pair identities below.

*  $a \rightarrow b$  (via  $\text{funSpaceEquiv}$ ).  $\text{lamComb } a \ b$ 's action, transported through  $\text{funSpaceEquiv}$ 
(Theorem 3.10,  $(\text{funSpace } U \ U) \cdot \text{Element } ? \circ \text{ApproximableMap } U \ U$ ), is exactly Scott's map-level
formula  $f \mapsto b \text{ comp } f \text{ comp } a$  ( $\text{toApproxMap\_toElementMap\_lamComb}$ , chaining  $\text{toElementMap\_curry\_apply}$ ,
 $\text{toElementMap\_prodMap\_pair}$ ,  $\text{evalMap\_apply}$ ). Both closure facts then reduce to the same
algebra as  $a \times b$ , transported back through the order-embedding  $\text{toApproxMap}$ .

*  $a+b$  (direct, no bridge to  $\text{sumMap}$ ).  $\text{sumMap}$ 's raw relation (Exercise319Sum.lean) is
not literally built from  $\text{cond} / \text{which}$ , so there is no equally cheap  $\text{sumComb} = i_+ \text{ comp } \text{sumMap} \text{ comp } j_+$ 
bridge; instead both facts are proved directly from Scott's literal formula via the
elementwise
characterizations  $\text{cond\_toElementMap\_mem}$  (Exercise 3.26),  $\text{which\_mem\_zero/one}$ , and the
round-trip identities  $\text{inMap}_0 \text{ outMap}_0 \text{ eq\_of\_left} / \text{inMap}_1 \text{ outMap}_1 \text{ eq\_of\_right}$ , case-
splitting
on  $\text{sum\_element\_trichotomy}$ . Idempotence's bottom case additionally needs  $j \text{Plus\_bot\_eq\_bot}$ 
(an instance of the general  $\text{toElementMap\_bot\_eq\_bot\_of\_comp\_eq\_idMap}$ ): if  $j \text{ comp } i = I_D$ ,
then
 $j(E.\text{bot})$  is a lower bound of  $\text{all}$  of  $|D|$  ( $D.\text{bot} \leq i(v)$ , monotone through  $j$ ,
landing on
 $j(i(v)) = v$  -- take  $v := D.\text{bot}$  -- via  $j \text{ comp } i = I_D$ ), so  $j(E.\text{bot}) \leq D.\text{bot}$ , whence
 $v = D.\text{bot}$  by
antisymmetry with  $\text{bot\_le}$ ; no disjointness needed. The "reaches left"/"reaches right" case
formulas' own idempotence step does need the disjointness fact  $\text{not\_sum\_reaches\_both}$ 
( $\text{inj}_0 \text{ inter\_inj}_1 / \text{not\_sum\_mem\_empty}$ ) to rule out the other injection's guard in  $\text{which}$ ,
and
 $\text{inMap}_0 \text{ toElementMap\_reaches\_left} / \text{inMap}_1 \text{ toElementMap\_reaches\_right}$  (witnessed by the
master
neighbourhood) to re-enter the same case after one more application of  $a / b$ .

**Not attempted here: the second half of Proposition 8.10** (finitary-closure, i.e.
 $D_a * D_b \leq D_{\{a*b\}}$ ) -- this needs substantially more infrastructure (a general "conjugate

```

fixed-point-sets across a projection pair" lemma, plus `prodEquiv`/`funSpaceEquiv`/a coproduct-element characterization for `sum`) and is left as a documented follow-up; see `HANDOFF.md`.

Axiom footprint: everything here mentions `U`, so (as with `Definition89.lean`) it inherits `U`'s

own `Classical.choice` footprint -- `subseq {proptext, Classical.choice, Quot.sound}`, confirmed not new.

# Proposition 8.10 (Scott 1981, PRG-19), second half -- finitary-closure

**Proposition 8.10(b).** If  $a, b : ? \rightarrow ?$  are finitary (projections), then so are  $a+b$ ,  $a \times b$ ,
 $a \rightarrow b$ , and moreover  $D_{a+b} \approx D_a + D_b$ ,  $D_{a \times b} \approx D_a \times D_b$ ,  $D_{a \rightarrow b} \approx$ 
 $(D_a \rightarrow D_b)$ , where
 $D_a$ ,  $D_b$  are the (witnessing) domains of  $a$ ,  $b$ .

## Strategy

For a finitary projection  $a : ? \rightarrow ?$ , Theorem 8.6's sub_eq_self_of_isFinitaryProjection
gives
 $a = \text{retractionOfSubsystem}(\text{fixedNbhd\_subsystem } a)$ , i.e.  $a = i_a \text{ comp } j_a$  for the
canonical
injection/projection pair  $i_a : D_a \rightarrow ?$ ,  $j_a : ? \rightarrow D_a$  of Proposition 6.12, where
 $D_a := \text{fixedNbhd } a$  is a genuine subsystem of  $?$  (Theorem 8.5). This is Scott's " $D_a$ " made
concrete and computed with directly (rather than via the abstract IsFinitary witness).

The key generic tool (elementIsoOfProjectionPair below) is Proposition 8.2's elementIso,
generalized away from requiring a literal  $D \subseteq E$  subset relation to an arbitrary
approximable
projection pair  $i : D \rightarrow E$ ,  $j : E \rightarrow D$  with  $j \text{ comp } i = \text{id}_D$  (no requirement  $i \text{ comp } j \leq \text{id}_E$ , and no
requirement that  $D$ ,  $E$  share a token type) -- exactly what theorem_8_8_b_strong's fixed
maps
 $i_+/j_+$ ,  $i_-/j_-$ ,  $i_- \rightarrow /j_- \rightarrow$  (Definition 8.9) are. Given such a pair and  $g = i.$ 
 $\text{comp } j$ , it
produces D.Element ?o Fix(g) directly.

For each combinator  $*$  in  $\{+, \times, \rightarrow\}$  we build a new projection pair  $I : D_a * D_b \rightarrow ?$ ,
 $J : ? \rightarrow D_a * D_b$  (composing Definition 8.9's fixed maps with the functorial action of  $*$ 
on
 $i_a, j_a, i_b, j_b$ ) and show algebraically (via the functor laws of  $\times$   $/+$   $/\rightarrow$  on maps,
plus
 $i_a.\text{comp } j_a = a$ ,  $i_b.\text{comp } j_b = b$ ) that  $J.\text{comp } I = \text{idMap } (D_a * D_b)$  and
 $I.\text{comp } J = a * b$ . elementIsoOfProjectionPair then hands us
 $(D_a * D_b).\text{Element ?o Fix}(a * b)$  directly, both witnessing IsFinitary (a * b) and Scott's
"moreover" isomorphism claim in one shot.

* **  $\times$  ** uses Exercise 3.19/3.20's prodMap and its functor laws prodMap_id/prodMap_comp
directly -- no new infrastructure needed.
* **  $+$  ** needs a modest amount of new infrastructure for sumMap (Exercise 3.19's sum functor
):
its own elementwise case-split formulas (mirroring Proposition810.lean's sumComb formulas
)
and its functor laws sumMap_id/sumMap_comp, built here.
* **  $\rightarrow$  ** needs a generalization of lamComb's construction (expMap, the Hom-functor's
action
 $f \mapsto k \text{ comp } f \text{ comp } h$ ) away from self-maps of  $?$  to a genuine bifunctor funSpace
 $V_0 V_1 \rightarrow$ 
funSpace V_0' V_1' for  $h : V_0' \rightarrow V_0$ ,  $k : V_1 \rightarrow V_1'$ , together with its functor
laws.

Axiom footprint: everything here mentions U, so it inherits U's own Classical.choice
footprint, subseq {propext, Classical.choice, Quot.sound}, confirmed not new (same as
Proposition810.lean/Definition89.lean).

/-! ## The `+` case
```

Unlike the `x` case, `sumComb` is *not* literally `iPlus.comp ((sumMap a b).comp jPlus)` by `rfl` (Definition 8.9 builds it from `cond`/`whichMap` instead) -- but it *is* that map elementwise (`sumComb\_eq\_iPlus\_sumMap\_jPlus` below), by the exact same case-split already used for `isRetraction\_sumComb`/`le\_idMap\_sumComb` in `Proposition810.lean`. Given that bridge, the rest is verbatim the `x` case's algebra, now powered by `sumMap\_id`/`sumMap\_comp`. -/

Exercise 8.11 (Scott 1981, PRG-19, Lecture VIII)

```
> Let `Q` be the set of rational numbers and define a neighbourhood system by the equation
> `R = {[0,r] ? r in Q and 0 < r <= 1}`. Show that the following defines an approximable
  map
> `a : R -> R` : `[0,r) a [0,s] iff r < s or r = s = 1`. Show in addition that `a` is a
  projection
> where the fixed-point set of `a` is in a one-one correspondence with the real numbers between
> `0` and `1` inclusive. (Hint: recall Dedekind cuts and show ` $\leq$ ` matches ` $\sqsubseteq$ `.)
  Conclude that `a`
> is *not* finitary. (Hint: aside from `1`, there are no finite elements for `{x ? x = a(x)}`.)
```

Contents

```
* `R` -- the chain neighbourhood system `{[0,r] ? 0 < r <= 1}` over `?` (`ofNestedOrDisjoint`
  `, since
  the intervals are literally nested by `r`).
* `a` -- Scott's map (`aRel`), shown approximable (`Exercise811.a`).
* `isRetraction_a` / `isProjection_a` -- the two closure facts Scott asks for.
* `fixOrderIso` -- the order isomorphism `Fix(a) ?o Set.Icc (0:?) 1` realizing Scott's Dedekind
  -cut
  correspondence (`c := 1 - t` is the "cut point", `t` the represented real, chosen so that ` $\leq$ `
  ` $\leq$ `
  literally matches ` $\sqsubseteq$ `, i.e. `fixOrderIso` is monotone both ways by construction).
* `not_isFinitary_a` -- `a` is *not* finitary: if it were, `Fix(a) ?o Set.Icc (0:?) 1` would
  transport
  to *some* domain `F`'s element poset, but every non-bottom element of `Set.Icc (0:?) 1` fails
  Theorem 8.5's algebraic-compactness test (only `0`, matching Scott's lone finite element `
  False`, is
  compact) -- contradicting that `F` (being a domain) has a non-bottom *principal* element as
  soon as
  it has more than one element.
```

Everything here inherits the ambient `Classical.choice` taint of Mathlib's `?`/`?` order instances (as with `Definition87.lean`'s `?`); no *further* choice is introduced beyond that and one genuine classical case split (`by\_contra`) used for the compactness contradiction.

# Exercise 8.12 (Scott 1981, PRG-19, Lecture VIII) -- a `Nat`-presentation of `?`

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19, Exercise 8.12
(`sources/PRG19.md`, line 5142):

> Generalize the notation `2X + 1` for subsets `X ⊆ Nat` to sets of the form `2^k X +
  ?`, where
> `? < 2^k`. Let `V` be the non-empty finite unions of sets `2^k Nat + ?`. Show that `U ≈ V`
  and
> that the isomorphism is effective, thus obtaining another presentation of `U`.

## Status of this file: `V` is fully formalized; `U ≈ ? V` is a genuinely hard open item

This file formalizes `V` itself -- the neighbourhood system over `Nat` generated by residue
classes
`2^k Nat + ? = {n | n % 2^k = ?}` -- completely rigorously, along with its basic structural
facts

```

(closure under intersection, no minimal neighbourhoods). **It does not attempt the isomorphism**
``U ~ = ? V`` claimed by the exercise, for a substantive mathematical reason recorded here so a future session does not have to rediscover it.

Why "translate through real numbers" does not work

Order isomorphisms preserve compactness (``Theorem85.lean``), and compact elements are **exactly** the **principal** elements (also ``Theorem85.lean``, proved for **any** neighbourhood system). So if ``U ~ = ? V`` via some ``?``, then ``?(U.principal h)`` for ``h : U.mem [1/3, 2/3)`` must be ``V.principal h'`` for some **single** valid ``V`-neighbourhood` ``h' : V.mem W``. But ``[1/3, 2/3)`` has non-dyadic rational endpoints, and **no** finite union of residue classes ``2^k Nat + ?`` equals it exactly (dyadic boundaries never land on thirds). So the naive map "restrict a ``U`-filter to its trace on dyadic-translated neighbourhoods" is provably not the right map at the level of individual (finite-union) neighbourhoods -- it is not merely hard to make effective, it loses information.`

Why the isomorphism is nonetheless very likely true, via a different technique

The fix is not to match single ``U`-neighbourhoods` to single ``V`-neighbourhoods` pointwise, but to match the **entire** (richly overlapping, atomless) neighbourhood posets via a **computable back-and-forth** construction: both ``U`` and ``V`` are countable, have no minimal neighbourhoods (``U_no_minimal``, and the ``V`-analogue` would need to be proved -- every ``2^k Nat + ?`` splits into two disjoint proper residue-class-unions), and are rich enough (via **finite unions**, not just single basic pieces) to realize arbitrary "overlapping split" configurations on either side. This is exactly the shape of the classical fact that any two countable atomless dense structures of the same signature are isomorphic (a la back-and-forth for dense linear orders without endpoints), made **effective** here (matching the exercise's "the isomorphism is effective").

Turning this into a Lean proof requires, at minimum:

1. A **general, reusable lemma**: two effectively-presented, atomless neighbourhood systems satisfying a suitable "one-step extension" property (any finite partial order/consistency preserving matching between their neighbourhoods extends to accommodate one more neighbourhood from either side) are effectively isomorphic. No such lemma exists yet anywhere in this project.
2. A proof that ``U`` and ``V`` **each** satisfy that extension property -- itself a real combinatorial argument on both sides (splitting existing matched pieces finely enough via density of ``?``, resp. of dyadic residues).
3. Assembling the actual computable back-and-forth enumeration and proving it effective.

This is comparable in size to ``Theorem88``'s universality proof and was **explicitly deferred** (see ``HANDOFF.md``) rather than attempted in a single pass, to avoid a long, high-risk excursion with uncertain payoff. ``V``'s own effective presentation (``ComputablePresentation V``, mirroring ``UComputablePresentation.lean``) is **also** deferred for the same reason (it needs genuine ``Nat.Primrec`` bit-manipulation infrastructure -- "upsample a bitmask from level ``k`` to level ``k``" -- that does not exist yet); only the non-computable mathematical content is proved here.

What **is** proved here

``affine k ? = {n | n % 2^k = ?}``, Scott's ``2^k Nat + ?`` (for ``? < 2^k``; automatically ``{}``

```

    otherwise).
* `levelSet k m = {n | m.testBit (n % 2^k) = true}`, the *bookkeeping-free* encoding of "the
  union of
  residue classes `?` (for `? < 2^k`) with `m.testBit ?`" -- mirroring `Definition87.lean`'s
  `presentedIntervals`, but every finite union at a fixed level `k` is captured by a single
  bitmask
  `m` instead of a list, since residue classes at a common level partition `Nat` into finitely
  many
  pieces (unlike arbitrary rational intervals).
* `upsample k k' m`: re-expresses a level-`k` bitmask at a finer level `k' >= k` (each
  residue class
  becomes the union of the finer residue classes refining it), built via `Nat.equivBitIndices`
  rather than raw bit-shifting arithmetic (cleaner to reason about; a genuinely computable
  version
  is exactly the missing "Primrec bit-manipulation infrastructure" mentioned above).
* `levelSet_inter`: `levelSet k_1 m_1 I levelSet k_2 m_2` is again a `levelSet`, so no
  consistency
  hypothesis is needed for closure (mirroring `Example78.lean`'s `PN`, unlike `Definition87.
  lean`'s
  `U` which genuinely needs one).
* `V : NeighborhoodSystem Nat`, `V_no_minimal` (Scott's remark after Definition 8.7,
  transplanted).
* `V_mem_iff_finiteUnion`: faithfulness -- `V.mem` (the bookkeeping-free `levelSet`-based
  definition)
  agrees exactly with Scott's literal "finite unions of `2^k Nat + ?`" description.

## Axiom footprint

No `Classical.choice`, `Classical.dec`, or nonconstructive existence appears anywhere in this
file
(changed by inspection -- every proof is `Nat.testBit`/`Nat.equivBitIndices`/arithmetic
reasoning).
`#print axioms` nonetheless reports `[propext, Classical.choice, Quot.sound]` starting from the
most
elementary lemmas (`levelSet_nonempty_iff`, which uses only `Nat.mod_lt`/`positivity`), so the
`Classical.choice` footprint is an *upstream* artifact of this Mathlib snapshot's `Nat`/`Finset`
`Set`
API -- the exact same phenomenon `Definition87.lean` documents for `?`'s order instance (there,
even
`Rat.le_refl` reports this footprint) -- not a choice made in this file.

# Exercise 8.12(b) (Scott 1981, PRG-19, Lecture VIII) -- `V`'s computable presentation

Builds the `Nat.Primrec` bit-manipulation infrastructure `Exercise812.lean`'s docstring flagged
as
missing ("upsample a bitmask from level `k` to level `k'`, computably"), and assembles it into
a
genuine `ComputablePresentation V`, closing Exercise 8.12(b).

## Design

Mirrors `UComputablePresentation.lean`'s two-layer shape (canonicalize an arbitrary code, then
wire
Scott's two relations) combined with `Example78.lean`'s choice-free bit-level idiom (`myLor`,
built
by hand since mathlib's `Nat.lor`/`Nat.testBit` are not exposed as `Nat.Primrec`):

* **Bit extraction** (`myDivPow2`/`myTestBit`): `Nat.Primrec` versions of `n |-> n / 2^?` and
`n |-> n.testBit ?`, built by iterating "halve" `?` times via `Nat.Primrec.prec` (the same
"iterate a step a data-dependent number of times" idiom `primrec_foldCode`/`myLor` already
use).
* **`myLand`** (bitwise AND): a hand-built choice-free primitive-recursive `&&&`, mirroring `
myLor`
bit-for-bit (literally: `lowOr`/`lorStep` become `lowAnd`/`landStep`, `Nat.testBit_lor`
becomes
`Nat.testBit_and`).
* **`myUpsample`** (the missing piece): re-expressing a level-`k` bitmask at level `k'`  $\geq k$ .
The key
realization is that `Exercise812.lean`'s `upsample`'s one-level step is arithmetic, not
bit-by-bit: doubling `m` from level `k` to `k+1` duplicates its low  $2^k$  bits into a second
copy
shifted up by  $2^k$  positions, i.e.  $m' + m * 2^{(2^k)}$  where  $m' := m \% 2^{(2^k)}$  is
`m`'s
low  $2^k$ -bit truncation (`myModPow2`, itself built from `myDivPow2`). Truncating first
avoids any
addition-carry ambiguity from `m`'s "junk" bits at positions  $\geq 2^k$  (irrelevant to `
levelSet k m`
as a set, but would corrupt a naive  $m + m * 2^{(2^k)}$ ). Iterating this step `k' - k` times
(again
via `Nat.Primrec.prec`, jointly tracking the current level alongside the mask, exactly as `
lorStep`
jointly tracks two running arguments) gives `myUpsample`.
* **Nonemptiness** (`myLevelSetNonempty`): `(levelSet k m).Nonempty <-> exists ? < 2^k, m.
testBit ?`
(`levelSet_nonempty_iff`) is a bounded `exists` of a decidable predicate, handled by the
existing
`bExistsFn` combinator with `myTestBit` as the body -- no new quantifier infrastructure
needed.
```

* **Canonicalization** (``canonIdx`/`VX``): exactly ``UComputablePresentation.lean``'s ``canonCode`` pattern, but simpler (no "clip to ``[0,1)``" step is needed -- a ``(k, m)`` pair is always a **syntactically** well-formed level/mask pair, only possibly empty): keep a code ``n = pair k m`` unchanged if ``levelSet k m`` is non-empty, else fall back to the fixed master code ``pair 0 1`` (``levelSet 0 1 = univ``, ``levelSet_zero_one``).

* **Scott's two relations reduce to bitmask arithmetic**: ``Vinter n m``'s raw intersection is ``myUpsample`-both-then-`myLand`` at the joint level ``max k_1 k_2`` (mirroring ``levelSet_inter`` exactly), and consistency reduces to that merged mask being non-empty (``myLevelSetNonempty``); equality of two canonicalized codes' ``levelSet``s reduces to equality of their masks **after** upsampling both to a common level (``levelSet`` is injective in the mask at any fixed level, ``levelSet_inj_of_common_level``), decided by ``RecDecidable.natEq``.

Everything here is choice-free by construction (``Nat.Primrec`` terms built from the seven base combinators plus already-choice-free helpers); the correctness **lemmas** connecting these to ``Exercise812.lean``'s ``Set`-level `levelSet`/`upsample`` go through ordinary ``Nat`` arithmetic (``Nat.testBit_eq_decide_div_mod_eq``, ``Nat.testBit_and``, ``Nat.div_add_mod``, ...), which -- like every other file in this project touching ``Nat``'s order/decidability API -- reports the same inherited ``Classical.choice`` footprint documented in ``Definition87.lean``/``Exercise812.lean``, not a new choice introduced here.

/#!/ ### `myUpsample`: a computable version of `Exercise812.lean`'s `upsample`

The one-level step is *arithmetic*: `myUpsampleStep k m := 2 ^ (2 ^ k) * m' + m'` where
`m' := myModPow2 m (2 ^ k)` is `m`'s low-`2^k`-bit truncation. Truncating first is what makes
the
formula correct regardless of any "junk" bits `m` may carry at positions `>= 2^k` (irrelevant
to
`levelSet k m` as a set, but would corrupt a naive `m + m * 2^(2^k)`): mathlib's
`Nat.testBit_two_pow_mul_add` handles exactly the "low/high digit" splitting this needs, given

```

```

    the
truncation bound `myModPow2_lt`. -/

/-- One computable upsampling step: re-express a level-`k` mask at level `k + 1` by duplicating
its
low `2^k` bits into a second copy shifted up by `2^k` positions. -/

# Exercise 8.12(e)(d)(i) (Scott 1981, PRG-19, Lecture VIII) -- minimal-level canonicalization

```

```

`SplitV.lean`'s `splitVLeft`/`splitVRight` `(e)(b)` split a `V`-code `n = pair k m` by
  upsampling
one more level and taking a residue class *at level `k + 1`* -- but `V`'s codes are highly
non-canonical (`canonIdx` only collapses the "empty -> master" case, `LevelSetPrimrec.lean`),
  so the
*same* set `VX n` can be presented at arbitrarily many different levels `k`, and the residue-
  class
modulus  $2^{k+1}$  used by the split is not an invariant of the set, only of the
presentation. Concretely: `evens` presented at `(k, m) = (1, 1)` splits into residue classes
  mod
`4`; the *same* set presented at `(k, m) = (2, myUpsample 1 2 1)` splits into residue classes
  mod
`8` -- genuinely different output sets. This breaks `ComputableBisection.left_congr`/`
  right_congr`.

```

This file supplies the fix: a presentation-independent canonical `(level, mask)` pair for any `(k, m)`, found by searching for the *smallest* level `j ≤ k` at which `levelSet k m` is *also* presentable (`minLevel`), together with the (necessarily unique, `minLevel\_unique`) mask witnessing it at that level (`minMask`). `(e)(d)(ii)` will reroute `splitVLeft`/`splitVRight` through this canonicalization instead of `canonIdx`'s raw (possibly non-minimal) level, making the two outputs depend only on `VX n`, not on `n` itself.

Design

```

* isPeriodicMask k j m **: ({0,1}-valued, `Nat.Primrec`): decides whether upsampling `m`'s
  own
  low  $2^j$ -bit truncation from level `j` back up to level `k` reproduces `m`'s own low
   $2^k$ -bit truncation, i.e. whether `levelSet k m` is also presentable at level `j` -- via
  the
  very presentation `myModPow2 m (2^j)` built from `m` itself (`isPeriodicMask_iff`). This is
  an
   $O(1)$  formula (no bounded loop over bit positions needed), built from the already-primitive-
  recursive `myUpsample`/`myModPow2` plus the standard "isZero" of a two-sided truncated
  subtraction" equality decider (`Exercise724.lean`'s idiom).
* minLevel k m **: the smallest `j ≤ k` with `isPeriodicMask k j m = 1`, found by the
  exact same
  bounded `Nat.rec`-fold search `myFirstBit` uses (`SplitV.lean`), substituting `isPeriodicMask
  k i m`
  for `myFirstBit`'s `myTestBit m i` test. The search always succeeds by `j = k` itself
  (`isPeriodicMask_self`), so the sentinel `k + 1` is never actually witnessed for genuine
  inputs.
* minMask k m := myModPow2 m (2^minLevel k m) **: `m`'s own bits, truncated to the minimal
  level's width.
* levelSet_minLevel **: `(minLevel k m, minMask k m)` presents the same set as `(k, m)`
  (immediate from `minLevel k m`'s own defining periodicity fact).
* minLevel_unique (the crux): if `(k_1, m_1)` and `(k_2, m_2)` present the same set,
  their
  minimal presentations agree exactly (`minLevel k_1 m_1 = minLevel k_2 m_2` and
  `minMask k_1 m_1 = minMask k_2 m_2`). The genuinely new content, beyond `minLevel`'s own
  inductive
  search spec (mirroring `myFirstBit_spec`) and the existing injectivity/upsample machinery
  (`levelSet_inj_of_lt`, `levelSet_eq_iff_myUpsample_eq`), is a short elementary argument
  (`levelSet_presentable_imp_self`) showing that if a set `levelSet k m` happens to be
  presentable
  at some smaller level `j ≤ k` via any witness mask at all, it is already presentable
  there via
  the canonical witness `myModPow2 m (2^j)` built from `m` alone -- by directly cross-
  substituting
  the level- $j$ /level- $k$  presentation hypothesis at `n = i` and `n = i % 2^j` for each bit
  position `i < 2^k`, with no induction needed.

```

# Exercise 8.12(c) (Scott 1981, PRG-19, Lecture VIII) -- a general two-sided back-and-forth
lemma

```

Following the 7-part plan recorded in `arxiv.md`/`HANDOFF.md`, this file works towards **Exercise 8.12(c)**: a new, general (non-effective) lemma that two countable, atomless neighbourhood systems, each satisfying a mutual one-step extension property relative to the other, are order-isomorphic.

A structural shortcut over `Theorem88.lean`'s one-sided embedding

`Theorem88.lean`'s back-and-forth (`exists\_split`/`atomU`/`Yseq`) embeds an *arbitrary* countable `D` into `U` by tracking a matching pair `(A, B)` where only the `U`-side `B` is kept a genuine `U`-neighbourhood-or-{} at every step (via `U\_no\_minimal`); the `D`-side atom `A` is *never* required to be a `D`-neighbourhood -- it is an uninterpreted Boolean combination of `D`'s own sets and their *complements* ($\Delta \setminus X_i$), which need not lie in `D` at all. This asymmetry is exactly what makes a one-sided *embedding* enough, but is also exactly what breaks for a genuine two-sided *isomorphism*: to alternately refine *both* sides (sometimes splitting `D\_0`'s atom via `D\_0`'s own no-minimal property, sometimes `D\_1`'s), the side not currently being split still needs to remain a genuine neighbourhood-or-{} at every step, including right after being intersected/subtracted by an enumerated neighbourhood from the *other* side.

Key discovery: both `U` and `V` are already *Boolean-closed* -- closed not just under consistent intersection (Definition 1.1(ii)) but under *set-difference* of any two of their own neighbourhoods (`U\_diff\_mem`, `V\_diff\_mem` below), on top of their already-known closure under finite union (`U\_union\_mem`/`V\_union\_mem`) and unconditional/positive intersection (`U`'s `combineIntervals`, `V`'s `levelSet\_inter`, both witness-free). `U`'s case is nearly free:

`IntervalPrimrec.lean`'s `diffLists`/`presentedIntervals\_diffLists` (built for the *computable* presentation, Exercise 7.22-style) already witnesses this unconditionally, so `U\_diff\_mem` is a two-line corollary. `V`'s case is the bitmask arithmetic identity $a \wedge (a \&\&\& b) = a$ and not b , mirroring `levelSet\_inter`'s own `upsample`-then- $\&\&\&$ formula.

Boolean-closure means a *complement-relative-to-master* is always *mem-or-{}* ($X \setminus D.\text{master}$, or rather $D.\text{master} \setminus X$, is a special case with $Y := D.\text{master}$), and hence *every* finite Boolean combination of enumerated neighbourhoods and their complements (`genAtom`, `Theorem88.lean`'s own notion) is *automatically* *mem-or-{} by a direct induction* -- no `Classical.choice`-driven splitting needed to keep either side "in the family". This is the structural fact that will let the two-sided construction alternate which side is intersected/subtracted (a free computation) against which side is split via the *other* system's no-minimal property (the one place non-constructive choice genuinely enters, exactly as in `Theorem88.lean`), symmetrically.

Status

This file establishes:

1. The Boolean-closure prerequisites `U\_diff\_mem`/`V\_diff\_mem` (and `U\_isPositive`/`V\_isPositive`, `U\_noMinimal`/`V\_noMinimal` repackaging the existing `U\_no\_minimal`/`V\_no\_minimal`).
2. The generic definitions (`NeighborhoodSystem.NoMinimal`, `.DiffClosed`) the back-and-forth

```

is
  stated over, plus `genAtom_mem_or_empty` (Boolean atoms are automatically mem-or-{} -- no
  choice
  needed) and its one-step building blocks `inter_mem_or_empty`/`diff_mem_or_empty`.
3. `exists_split`/`SplitSpec`/`splitChoice`: `Theorem88.lean`'s `exists_split`/`SplitSpec`/
  `splitChoice`, generalized from the hardcoded target `U` to an abstract atomless `E`.
4. **`atomPair`/`atomPair_invariant`**: the interleaved two-sided atom construction and its
  core
  invariant (matched emptiness, mem-or-{} on both sides at every depth). This is the technical
  heart
  of the two-sided back-and-forth -- see the section docstring above `atomPair` for the
  construction.

**Not yet done** (tracked as 8.12(c)'s remaining work): pairwise disjointness of `atomPair`
  across
  disagreeing sign sequences (needed for a `Yseq`-style closed form on *both* sides at once), the
  resulting `Xseq`/`Yseq`-analogue transfer lemmas (subset/inter-empty/inter-eq, mirroring
  `Theorem88.lean`'s `transfer_subset_iff`/`transfer_inter_eq_iff` but bidirectionally), and the
  final
  assembly into `DomainIso D_0 D_1`. This remaining work is comparable in size to the rest of
  `Theorem88.lean` (`Yseq` onward) plus `Theorem88a.lean`'s assembly, done twice (once per
  direction)
  plus the interleaving glue -- a substantial next increment, tracked in `HANDOFF.md`.

/-! ### Boolean atoms are automatically mem-or-empty

The key structural payoff of Positivity + difference-closure: `Theorem88.lean`'s `genAtom`
(a finite Boolean combination of an enumerated family `Z 0, ..., Z (n-1)` and their complements
relative to `M`) is *automatically* `D.mem-or-{}`, by a direct induction -- no
`Classical.choice`-driven splitting is needed to keep it "in the family". This is what will let
the
eventual two-sided back-and-forth alternate which side is refined by plain intersection/
difference
(free) against which side is refined by the *other* system's `NoMinimal` property (the one
place
genuine choice enters, exactly as in `Theorem88.lean`). -/
theorem genAtom_mem_or_empty {? : Type*} {D : NeighborhoodSystem ?} (hpos : D.IsPositive)

/-! ### The two named sub-steps of `atomPair`, as instances of `xyStep`

These, and their basic subset/disjointness properties, are stated fully generically (
  independent
of any particular `D_0`/`D_1`/`X`/`Y`) and placed here, *before* `section AtomPair` below, so
  that
they do not pick up that section's `include`d hypotheses (`hD_Opos`, `hXmem`, etc.) as spurious
extra arguments -- `xStep`/`yStep` only ever need a *single* system's data (`D_1`/`hD_1nomin`
  for
`xStep`, `D_0`/`hD_0nomin` for `yStep`), never the full two-sided context. -/

/-- **The `X`-sub-step**, as an instance of `xyStep`: split `D_1`'s side while directly
  refining
`D_0`'s side. -/

/--- ### A generic union-closure fact for `IsPositive` + `DiffClosed` systems

Needed by 8.12(c)(vi)(3)'s `YseqE_empty_or_mem`: `Theorem88.lean`'s own `U_union_mem`/
`U_iUnion_mem` (`Definition87.lean`) are proved directly from `U`'s presented-interval
structure
(list `++`), which an abstract `E` does not have access to. But `IsPositive` + `DiffClosed` +
`sub_master`, entirely on their own, already force closure under finite union via the De Morgan
identity `X U Y = M \ ((M \ X) I (M \ Y))` (valid whenever `X, Y subseq M`) -- `M \ X
`/`M \ Y` are
mem-or-{} by `DiffClosed`, their intersection is mem-or-{} by `IsPositive`, and one more `
DiffClosed`
application finishes it. This is genuinely new generic content (`U`/`V`'s own union-closure
lemmas
never needed to be derived this way), not a transcription of anything in `Theorem88.lean`. -/

theorem union_eq_master_diff_inter_compl {? : Type*} (M X Y : Set ?) (hX : X subseq M) (hY

/#!/### The interleaved two-sided atom construction

Fix `D_0 : NeighborhoodSystem a`, `D_1 : NeighborhoodSystem b`, each Positive, difference-
  closed and
atomless (`NoMinimal`), with enumerations `X : Nat -> Set a`, `Y : Nat -> Set b` covering `
  D_0.mem`/`D_1.mem`
respectively. `atomPair` tracks a matched pair `(A, B) : Set a x Set b`, refined by *two* sub
  -steps
per index `n`: an **X*-step** (test `A` against `X n` directly -- free by Boolean-closure --
  and
correspondingly split `B` via `D_1`'s `NoMinimal`, exactly `Theorem88.lean`'s `exists_split`
  with
`E := D_1`), followed by a **Y*-step** (symmetrically: test the *new* `B` against `Y n`
  directly,
and split the *new* `A` via `D_0`'s `NoMinimal`, `E := D_0`). A sign sequence `? : Nat ->
  Bool x Bool`
selects the `+`/`-` branch at each of the two sub-steps. -/

/-! ### Pairwise disjointness of `atomPair` (Exercise 8.12(c)(v))

Mirrors `Theorem88.lean`'s `atomU_invariant`'s third clause, but proved on both sides at
once.
Two supporting facts are needed first: `atomPair_congr` (agreeing sign sequences below `n` give
the
identical depth-`n` pair -- no invariant needed, purely definitional) and `atomPair_fst_subset`
`/
`atomPair_snd_subset` (each side only shrinks from depth `n` to `n+1` -- does need the
invariant,
since the shrinking is via `split_fst_subset`/`split_snd_subset`, which only fire once the
`SplitSpec` preconditions are known to hold). -/

omit hD_0pos hD_0diff hD_1pos hD_1diff hXmem hYmem hD_0mne hD_1mne in
/-- Extending/changing `` at or beyond position `n` does not change `atomPair ? n` (mirrors
`Theorem88.lean`'s `atomU_congr`/`genAtom_congr`; needs no invariant, since every step is an
ordinary function of its inputs). -/

/-! ### Exercise 8.12(c)(vi)(4): recovering `X n` on `D\_1`'s side directly from `atomPair`

```

**Correcting the original pre-plan.** The plan (`arxiv.md`/`HANDOFF.md`, written before any
code)
anticipated a *bridge* identifying `atomPair`'s per-side trajectory with an instance of
`Exercise812cYseq.lean`'s single-family `atomE` (`E := D_1` for the `X`-sub-step, `E := D_0`
for the
`Y`-sub-step). **This turns out to be false**, not just difficult: `atomE`'s testing family
`genAtom X Delta ? n` is a *free* Boolean combination (only ever intersected/subtracted
directly,
never split), whereas `atomPair`'s `A`-component is *itself* choice-split at every `Y`-sub-step
(via `D_0.NoMinimal`) -- so whenever `exists_split`'s genuine-split case fires (generically),
the
actual `A_n` is a *proper* subset of `genAtom X Delta ?_1 n` (`?_1 k := (? k).1`), with
different
emptiness. Concretely: both `atomPair` components are "`atomE`-like" (choice-driven), so *
neither*
is "`genAtom`-like" (free) -- unlike `Theorem88.lean`'s one-sided case, where `D`'s side stayed
free
by construction. `Exercise812cYseq.lean`'s apparatus therefore is **not** reused here (it
remains
valid, reusable general theory for any genuinely one-sided abstract `E`, just not what this
specific
bridge needs).

**The actual fix**, found by re-deriving `Yseq`'s "I-formula" argument directly against `
atomPair`,
reusing only `atomPair_invariant`/`atomPair_congr`/`atomPair_disjoint` (already `Pass`, (iv)/(v
))
and `xStep_snd_subset` (already `Pass`, (v)(2)) -- no `atomE` involved: `XPseq n` unions, over
all
depth-`n` histories, the `D_1`-piece obtained by the `X`-sub-step's "+" branch (the *half-step*
value, strictly before the following `Y`-sub-step further refines it). This is *simpler* than
`Yseq`'s own proof in one respect: since the branch is a literal argument (`true`) rather than
`? n`'s own value, there is no need for `Theorem88.lean`'s `Function.update`-based "`?2`"
detour --
agreement below `n` alone suffices. -/

open Classical in
/-- **`XPseq`**: the union, over all depth-`n` histories, of the `D_1`-piece chosen by the
`X`-sub-step's "+" branch against `X n`. Recovers `X n`'s correspondent on `D_1`'s side (the
two-sided, half-step analogue of `Theorem88.lean`'s `Yseq`). -/

/-! ### Exercise 8.12(c)(vi)(4)(b)-(d): recovering `Y n` on `D_0`'s side directly from `
atomPair`

Symmetric to `XPseq` above, but genuinely harder: `yStep`'s own inputs (the *post*`-`X`-sub-step
values `A1`/`B1`) already depend on `( ? n ).1` itself, not just history strictly below `n` --
unlike
`xStep`'s inputs (`atomPair ? n`), which depend only on history strictly below `n`. So `YPseq`'
s
union needs an *extra* free `Bool` parameter `bx` for position `n`'s `X`-sub-step bit ((b)
below),
and relating an arbitrary such `bx` back to a concrete history's own bit needs a
`Function.update`-style bridge ((c) below, `xStep_spec_bit`, a drop-in generalization of
`xStep_spec` to an arbitrary bit rather than ` ? n`'s own) before the "I-formula" itself ((d))
can
go through. -/

open Classical in
/-- **`YPseq`** (8.12(c)(vi)(4)(b)): the union, over all depth-`n` histories *and* a free `Bool
`
`bx` for position `n`'s `X`-sub-step bit, of the `D_0`-piece chosen by the `Y`-sub-step's "+"
branch
against `Y n`. Recovers `Y n`'s correspondent on `D_0`'s side. -/
noncomputable def YPseq (n : Nat) : Set a :=

/-! ### Exercise 8.12(c)(vi)(5): `XPseq`/`YPseq` are always `D_1`/`D_0`-mem-or-{}

**First, achievable piece.** The full pre-planned content of (vi)(5)/(vi)(6) -- an order/
intersection
"transfer" layer recovering facts like `X i subseteq X j <-> XPseq i subseteq XPseq j` (
mirroring `Theorem88a.lean`'s
`embed_subset_iff`, needed for the eventual `DomainIso` assembly) -- turns out to need a
genuinely
new **joint two-family** atom/`genAtom`-style apparatus (testing points against *several* `X`
indices at once), not just the single-index `XPseq`/`YPseq` built in (vi)(4): unlike
`Theorem88a.lean`'s `idxSet` (always non-empty by pure index bookkeeping, independent of `D`'s
own
`mem` structure), `atomPair`'s atoms can genuinely vanish, so relating *two* indices' inclusion
needs evaluating a *joint* atom, exactly why `Theorem88.lean`'s own `genAtom`/`
transfer_empty_iff`
apparatus takes finite *lists* of constraints rather than single indices. That joint apparatus
is
real, substantial new work, not yet scoped -- deferred to a later sub-step once (vi)(5)/(vi)(6)
chart
its precise shape. **What *is* immediately available**, reusing (vi)(3)'s fully generic
`iUnion_mem_or_empty` (no new theory needed): `XPseq n`/`YPseq n` are themselves always `D_1`/`
D_0`
mem-or-{}, since each is a `Fintype`-indexed union of mem-or-{} pieces (`SplitSpec`'s own
guarantee

/-! ### Exercise 8.12(c)(vi)(5)(b): `atomPair` as a `genAtom` over an interleaved family

The interleaved families `combinedX`/`combinedY` and shared sign-interleaving map `combined?`
(mirroring `Theorem88.lean`'s `atomU_eq_genAtom`, but half-stepped): `combinedX` alternates
between
`X`'s own enumeration (even positions) and `YPseq`'s recovered `D_0`-side pieces (odd positions
);
`combinedY` alternates symmetrically between `XPseq` (even) and `Y` (odd); `combined?`
interleaves
`?`'s two components the same way. The headline facts, `atomPair_fst_eq_genAtom`/
`atomPair_snd_eq_genAtom` below, identify `atomPair ? n`'s two sides with `genAtom` over these
families at depth `2 * n` -- proved via the odd-depth half-step identities `
genAtom_combinedX_succ_eq`/
`genAtom_combinedY_succ_eq`, which in turn are exactly (vi)(5)(a)'s two closed-form lemmas
(`yStep_fst_succ_eq`/`xStep_snd_succ_eq`) each performed once per level of `n`, as anticipated.
-/

/-! ### Exercise 8.12(c)(vi)(7): the bidirectional "genuine neighbourhood" glue

The last ingredient (vii)'s `DomainIso` assembly needs beyond (5)'s order/intersection transfer
:
`X n`/`Y n` (being `hXmem`/`hYmem`'s enumerated sets) are *never* `{}` (`NoMinimal.mem_ne_empty`
`),
and -- via the `i = j` case of (5)(d)'s inter-empty transfer, collapsed through `Set.inter_self`
` --
neither are their `atomPair`-images `XPseq`/`YPseq`. Combined with `XPseq_empty_or_mem`/
`YPseq_empty_or_mem` ((vi)(4)), this makes `XPseq n`/`YPseq n` *always genuine* neighbourhoods
(`D_1`'s/`D_0`'s resp.), completing the correspondence: no separate "mutual extension"
hypothesis
beyond `NoMinimal` on both sides is needed. -/

# Exercise 8.12(c)(vi)(1) (Scott 1981, PRG-19, Lecture VIII) -- the abstract `Yseq` closed form

Generalizes `Theorem88.lean`'s core `Yseq` closed-form apparatus (`atomU`, `Yseq`,
`splitfst_eq_inter_Yseq`, `atomU_subset_master`, `atomU_succ_eq`, `atomU_eq_genAtom`) from the
hardcoded target `U : NeighborhoodSystem ?` to an abstract atomless `E : NeighborhoodSystem
?`**,
exactly mirroring how `Exercise812c.lean`'s `exists_split`/`SplitSpec`/`splitChoice`
generalized
`exists_split`/`SplitSpec`/`splitChoice`. Once done twice (once with `E := D_0`, once with
`E := D_1`, in 8.12(c)(vi)(5)/(vi)(6)), this is the machinery that recovers a closed-form
description of `atomPair`'s two interleaved sub-steps -- the two-sided analogue of Scott's `Y_n`
`.

## What is reused unchanged from `Theorem88.lean`

`extendTrue`/`restrictFin` (and their agreement lemmas `extendTrue_agree`/
`extendTrue_restrictFin_agree`) and the generic `genAtom` family (`genAtom`, `genAtom_subset`,
`genAtom_congr`, `genAtom_forward`, `genAtom_self`) are already fully type-generic** in
`Theorem88.lean` -- none of them mention `U` at all. They are imported and used verbatim*
below,
with no re-statement needed.

## What is new here

Everything downstream of `atomU` in `Theorem88.lean` (`atomU` itself onward) is hardcoded to
`U.master`/`U.mem`. This file re-proves that whole layer -- `atomE` (the `atomU`-analogue),
`atomE_invariant`, `YseqE` (the `Yseq`-analogue), `splitfst_eq_inter_YseqE`,
`atomE_subset_master`,
`atomE_succ_eq`, `atomE_eq_genAtom` -- against an abstract `E : NeighborhoodSystem ?` and an
abstract
`split` satisfying `SplitSpec` `E split` (`Exercise812c.lean`), taking `E.master.Nonempty` as an
extra explicit hypothesis (`U.master`'s nonemptiness was previously a hardcoded fact about
`[0,1]`);
for the eventual instantiations `E := D_0`/`E := D_1` this is exactly the `hD_Omne`/`hD_1mne`
hypothesis
already in scope in `Exercise812c.lean`'s `section AtomPair`. The finite-constraint transfer
lemma
(`transfer_empty_iff` and its corollaries) and the nonemptiness facts (`Yseq_empty_or_mem`/
`Yseq_nonempty_of_mem`) are deliberately not included here -- tracked separately as
8.12(c)(vi)(2)/(vi)(3).

# Exercise 8.12(d) (Scott 1981, PRG-19, Lecture VIII) -- effective refinement of 8.12(c)

## 8.12(d)(1): generalizing the core recursion over an abstract split

`Exercise812c.lean`'s `xStep`/`yStep`/`atomPair` are all built directly on top of the
**classical** `splitChoice` D_1 hD_inomin`/`splitChoice` D_0 hD_Onomin` (defined via `Classical
.choice`
over `exists_split``). To eventually get an effective isomorphism we need to re-run the exact
same
construction with a computable split instead -- so the first step is to generalize `xStep`/
`yStep`/`atomPair` (and its core invariant/disjointness/subset facts) over an abstract split
satisfying `SplitSpec``, rather than one hardcoded to come from `NoMinimal` via choice.

```

This turns out to be a comparatively light abstraction, because `Exercise812c.lean`'s own generic layer (`xyStep`, `xyStep\_disjoint\_of\_ne`, `SplitSpec`, `splitfst\_subset`, `split\_snd\_subset`) is

****already**** split-agnostic -- the hardcoding to `splitChoice` only happens at `xStep`/`yStep` themselves (`Exercise812c.lean` lines 390/398). So this file's job is: redo **just** `xStep`/`yStep` through `atomPair`'s subset/disjointness/master-subset facts (`Exercise812c.lean` lines 390-757) with the `NoMinimal`-witnessed `splitChoice` D_i hD_inomin replaced by an arbitrary `(splitX, hxSplit : SplitSpec'  $D_1$  splitX) / (splitY, hySplit : SplitSpec'  $D_0$  splitY) pair -- every proof step transcribes essentially verbatim, replacing `splitChoice`\_isSplitSpec  $D_i$   $hD\_inomin$  (a *\*term\**) with the hypothesis `hxSplit`/`hySplit` directly.

****Scope note** (adjustment from the original `arxiv.md` scoping, discovered during execution): ****the original scoping listed `XPseq`/`YPseq`/`combinedX`/`combinedY`/`toD1`/`toD0`/`domainIso812c` as also needing a parallel classical-abstract-split generalization in this sub-part. On closer inspection this is unnecessary extra work: those are all downstream consequences of `atomPair`'s invariant/disjointness/subset facts alone (never touching `splitX`/`splitY`/`hxSplit`/`hySplit` directly), so `(d)(3)`-`(d)(6)` can build the **code-level** analogues (`atomPairCode`, `XPseqCode`/`YPseqCode`, computability of `toD1`/`toD0`, final `EffectiveIso` assembly) directly on top of `atomPairG` below, without first needing a redundant **classical** abstract-split replica of the whole downstream chain. This keeps `(d)(1)` focused on the genuinely load-bearing recursive core that every later sub-part depends on.**

We also verify, as a sanity check that the abstraction is not vacuous and genuinely subsumes `Exercise812c.lean`'s construction, that instantiating `splitX := splitChoice'  $D_1$   $hD\_inomin$ `/`splitY := splitChoice'  $D_0$   $hD\_Onomin$ ` recovers `atomPair` exactly (`atomPairG\_splitChoice\_eq`)

/-- **8.12(d)(4)(d)(i): the one-step 4-way classical reunion, `D_1`-side.** The `D_1`-side
mirror of

```

```

`atomPairGfstunionstep`: ranging over all four `(b1, b2) : Bool x Bool` sign choices at
depth
`n`, the resulting depth-`(n+1)` `D_1`-pieces reunion to exactly the depth-`n` parent's `D_1`
-piece.
Genuinely simpler to prove than the `D_0`-side version: here the inner (`b2`-level)
collapse is
the hypothesis-free one (`yStepGsndunion`, `D_1`'s side is `yStep`'s own direct-refine side)
and
the outer (`b1`-level) collapse is the one needing `hXSplit` (`xStepGsndunion`, `D_1`'s
side is
`xStep`'s split side) -- exactly the reverse pairing from the `D_0`-side proof, so no per-
branch
`have`s (`hBAtrue`/`hAmemtrue`/etc.) are needed at all: `yStepGsndunion` takes no `SplitSpec`
hypotheses, so both inner collapses are immediate rewrites, leaving only the outer `
xStepGsndunion`
call. -/

/-! ## 8.12(d)(2): computable splits relative to two presentations

A split function `split : Set a -> Set ? -> Set a -> Set ? x Set ?` is *computable
relative to*
presentations `P` (of the `a`-side) and `Q` (of the `?`-side) when both of its outputs are
given by
a **primitive-recursive** function of the three input indices -- mirroring `IsComputableMap`'s
"transport the semantic relation to the integer indices" idea (Definition 7.2), but for a
genuine
*function* rather than a relation, so we ask for `Nat.Primrec` index functions with an exact
(rather than merely r.e.) correctness spec, matching `ComputablePresentation.inter`'s own shape
(a primitive-recursive intersection-index function, `inter_spec`).

This one structure serves **both** `splitX : Set a -> Set b -> Set a -> Set b x Set b`

```

```

(as
  `IsComputableSplit P_0 P_1 splitX`) and `splitY : Set b -> Set a -> Set b -> Set a x
  Set a` (as
  `IsComputableSplit P_1 P_0 splitY`, roles swapped) -- no separate `X`/`Y`-flavoured structure
  needed. -/

/-- **A split function is computable relative to two presentations** `P` (`a`-side), `Q` (`?-`-
  side)
when its two outputs are indexed by primitive-recursive functions of the three input indices
(indices of `A` in `P`, `B` in `Q`, `Xn` in `P`). Only the two index functions are data;
  primitive-
recursiveness and correctness (`posIdx_spec`/`negIdx_spec`) are `Prop`s, so this is choice-free
. -/
structure IsComputableSplit {a ? : Type*} {V : NeighborhoodSystem a} {W : NeighborhoodSystem ?}
  (P : ComputablePresentation V) (Q : ComputablePresentation W)
  (split : Set a -> Set ? -> Set a -> Set ? x Set ?) where
/-- Index (in `Q`) of `(split (P.X n) (Q.X m) (P.X k)).1`, as a function of the three input
indices `n, m, k`. -/
posIdx : Nat -> Nat -> Nat -> Nat
/-- Index (in `Q`) of `(split (P.X n) (Q.X m) (P.X k)).2`. -/
negIdx : Nat -> Nat -> Nat -> Nat
/-- `posIdx` is primitive recursive (on the `Nat.pair n (Nat.pair m k)` coding, matching
`RecDecidable_3`'s convention). -/
posIdx_primrec : Nat.Primrec (fun t => posIdx t.unpair.1 t.unpair.2.unpair.1 t.unpair.2.
  unpair.2)
/-- `negIdx` is primitive recursive. -/
negIdx_primrec : Nat.Primrec (fun t => negIdx t.unpair.1 t.unpair.2.unpair.1 t.unpair.2.
  unpair.2)
/-- `posIdx n m k` genuinely indexes the split's first output **whenever that output is
non-empty**. This is conditional (not `forall n m k, ... = Q.X (posIdx n m k)` outright) for
a load-
bearing reason found 2026-07-06 while repairing 8.12(g): `Q.X j` is *never* literally `{}` (
  every
  `ComputablePresentation` index is `Q.mem`-genuine, `Q.mem_X`), yet `SplitSpec` (`
  Exercise812c.lean`)
-- the abstract correctness contract `atomPairG`'s classical layer needs `splitX`/`splitY` to
satisfy -- *requires* `(split A B Xn).1 = {}` exactly when `A I Xn = {}`. An *unconditional
*
`posIdx_spec` is therefore jointly unsatisfiable with `SplitSpec` for *any* split function
whatsoever (not just a specific concrete one) -- see `arxiv.md`'s 8.12(g) rows for the full
argument. Weakening to "conditional on non-emptiness" is the fix: it costs nothing at any
  call
site that already knows (from context, typically via `SplitSpec`'s own emptiness <->
  clause) that
the relevant output is non-empty -- which is every existing use in this file -- while making
the
structure satisfiable by a genuine `Set`-valued split whose output is sometimes literally
`{}`. -/
posIdx_spec : forall n m k, (split (P.X n) (Q.X m) (P.X k)).1 != {} ->
  (split (P.X n) (Q.X m) (P.X k)).1 = Q.X (posIdx n m k)
/-- `negIdx n m k` genuinely indexes the split's second output whenever that output is
non-empty. See `posIdx_spec`'s docstring for why this is conditional. -/
negIdx_spec : forall n m k, (split (P.X n) (Q.X m) (P.X k)).2 != {} ->
  (split (P.X n) (Q.X m) (P.X k)).2 = Q.X (negIdx n m k)

end IsComputableSplit

/-! ## 8.12(d)(3)(a): `IsComputableDiff` -- the missing "diff index" prerequisite

`ComputablePresentation` (Definition 7.1) only makes intersection effective (`inter`/
`inter_spec`, guarded by the consistency decider `cons_computable`). `atomPairG`'s recursion
(`xStepG`/`yStepG`) needs the direct refinement `A \ Xn` to stay effectively indexed at every
step too (the "split" sub-step is handled by `IsComputableSplit` above), and Definition 7.1
  simply
has no such primitive for `X \ Y`. `IsComputableDiff` supplies exactly that, mirroring `inter`/
`inter_primrec`/`inter_spec`'s shape -- with `cons_computable`'s role (deciding consistency,
i.e. whether the operation's output is a genuine neighbourhood) played here by `diff_computable`
  .

Both `IsComputableSplit`'s clause `A \ Xn = {} <-> (split A B Xn).1 = {}` (`SplitSpec`)
  and
`NeighborhoodSystem.DiffClosed` (`X \ Y = {} </> D.mem (X \ Y)`), and no neighbourhood is `{}`
  under
`NoMinimal` together mean "`X n \ X m` is a genuine neighbourhood" and "`X n \ X m` is non-
  empty"
coincide propositionally; `diff_computable` is phrased as the existence form (matching
`cons_computable`'s own phrasing) so it stays a direct structural mirror, but every later sub-
  part
is free to read it as an emptiness decider via that coincidence. One structure serves both
`P_0` and `P_1` symmetrically -- no separate hypothesis needed per side. -/

/-- IsComputableDiff P: set-difference relative to the presentation `P` is computable --
  a
primitive-recursive `diffIdx : Nat -> Nat -> Nat` indexing `X n \ X m` whenever that
  difference is a
genuine neighbourhood (`diffIdx_spec`, mirroring `inter_spec` exactly), together with a decider
for that very side-condition (`diff_computable`, mirroring `cons_computable`). Only `diffIdx`
  is
data; the rest are `Prop`s, so this stays choice-free to state (any particular instance may
  of
course need `Classical.choice` to construct, exactly like `inter`/`cons_computable`
  themselves
would for an arbitrary effectively-given system). -/
structure IsComputableDiff {a : Type*} {V : NeighborhoodSystem a} (P : ComputablePresentation V
  ) where
  /-- Index of `X n \ X m`, as a function of the two input indices. -/
  diffIdx : Nat -> Nat -> Nat
  /-- `diffIdx` is primitive recursive (on the `Nat.pair` coding of `n, m`). -/
  diffIdx_primrec : Nat.Primrec (fun t => diffIdx t.unpair.1 t.unpair.2)
  /-- `diffIdx n m` genuinely indexes `X n \ X m` whenever that difference is (exactly) some
  `X k` -- i.e. whenever it is a genuine neighbourhood. -/
  diffIdx_spec : forall {n m : Nat}, (exists k, P.X k = P.X n \ P.X m) -> P.X (diffIdx n m)
    = P.X n \ P.X m
  /-- 7.1(i)-for-`X`: "`X n \ X m` is a genuine neighbourhood" is recursively decidable in
  `n, m`, mirroring `cons_computable`'s role for `I`. -/

/-! ## 8.12(d)(3)(b): the `X`-sub-step's code-level state transition

`atomPairG`'s recursion state at depth `n` is a pair `(A_n, B_n) : Set a x Set b`. At the
code
level we track it as a triple `(idx0, idx1, junk)`: `idx0`/`idx1` index `A_n`/`B_n` in `P_0`/`
P_1`
(meaningful only when `junk = 0`), and `junk` is a **single shared** flag for "`A_n = B_n = {}`"

Lean 4 source (lines 801–1200)

already". A single flag (rather than "one per side", as originally tentatively scoped) suffices
because `atomPairG_invariant`'s own `ihAB` clause `(d)(1)` already proves the two sides go
empty
**together** at every depth -- so a per-side flag would always just duplicate the other.

The `X`-sub-step (`xStepG`) refines `D_0`'s side **directly** (intersect/diff against `X n =
P_0.X n`
-- the presentation's own `n`-th neighbourhood; the eventual application enumerates *all* of `
P_0`'s
neighbourhoods this way, mirroring `Theorem88d.lean`'s `idxSet (e P) n`) and `D_1`'s side via
the
**split** `(d)(2)`'s `IsComputableSplit`. This sub-part builds that half-step as a single
`Nat.Primrec` function of a packed `(n, bit, state)` argument; `(d)(3)(c)` composes it with the
symmetric `Y`-sub-step into the full `n -> n + 1` transition. -/

/-! ### Direct-refinement decidability, extracted from `cons_computable`/`IsComputableDiff`

Two deciders, mirroring `Theorem88d.lean`'s `datumDec` extraction pattern (`Classical.choice`
via
`RecDecidable`'s bare existential, then `isOne`-wrapped so the result is *literally* `{0,1}`-
valued,
not just "`= 1` iff ..."): whether `X n I X m` (resp. `X n \ X m`) is empty. -/

/-! ## 8.12(d)(3)(c): the `Y`-sub-step, composed into the full `atomPairCodeState`

`ySubStep` is symmetric to `xSubStep` (refines `D\_1`'s index directly, `D\_0`'s index via the
 split
 `hSplitY`), using the **same** packed-argument convention (`xwN`/`xwB1`/`xwS`, reused unchanged

```

    since
they are pure `Nat`-arithmetic, not tied to `X`). `atomPairStep` composes one `xSubStep` then
one
`ySubStep` at the same depth `n`, and `atomPairCodeState` assembles the full recursion via
`Nat.Primrec.prec`, mirroring `Theorem88d.lean`'s `atomUCodeState`/`atomStep` exactly --
    including
reusing its `wY`/`wState` packed-argument projections for the *outer* `(bit-source, depth,
state)`
wrapping. The bit-source `k` supplies **two** bits per depth `(?(n).1`, `?(n).2`), peeled via
a
persistent `rem` field (divided by `4` each full step, mirroring `atomStep`'s `remK / 2`)
    carried
alongside the two-sided `packState2` triple in a fresh outer pairing, `packStateC`. -/

/#!/ ## 8.12(d)(3)(d): per-step correctness against `atomPairG`

Whenever the recorded state at depth `n` is non-junk, `atomPairIdx0`/`atomPairIdx1`'s packed
indices literally index `atomPairG`'s depth-`n` component (instantiated at `X := P_0.X`, `Y :=
P_1.X`, `? := deltaPair k`, the two-bits-per-depth sign sequence read off the bit-source `k`)
-- the
two-sided, code-level analogue of `Theorem88d.lean`'s `genAtom_atomUCode`. Unlike that single-
sided
account (where `UX` is a total surjection and the code is always meaningful), here both sides
codes are only meaningful when non-junk, so the statement is conditioned on `atomPairJunk = 0`
throughout. -/

/-- **The two-bits-per-depth sign sequence** read off a bit-source `k`, the `atomPairG`-shaped
analogue of `Theorem88d.lean`'s `deltaOf`: the depth-`i` nibble `(k / 4 ^ i) % 2` supplies `( ?
i ).1`,
and `(k / 4 ^ i / 2) % 2` supplies `( ? i ).2` -- matching exactly how `atomPairStep` peels two
bits
per depth from `rem` (`rem % 2`, `(rem / 2) % 2`, then `rem / 4`). -/
def deltaPair (k : Nat) : Nat -> Bool x Bool :=
  fun i => (decide ((k / 4 ^ i) % 2 = 1), decide ((k / 4 ^ i / 2) % 2 = 1))

  unfold deltaPair; simp

theorem deltaPair_snd_eq_true_iff (k i : Nat) : (deltaPair k i).2 = true <-> (k / 4 ^ i / 2)
  % 2 = 1 := by
  unfold deltaPair; simp

/#!/ ### `deltaPair` is `Nat.testBit` in disguise, two bits per depth

Mirrors `Theorem88d.lean`'s `deltaOf_eq_testBit` (`deltaOf k i = k.testBit i`), but reading *
two*
`testBit`'s per depth (`2 * i` for the `.1` component, `2 * i + 1` for `.2`) -- the base-`4`/two
-bit
analogue, needed below to reuse `Nat.eq_of_testBit_eq`/`Nat.testBit_lt_two_pow` verbatim for
the
"distinct bounded bit-sources disagree somewhere" fact (`(d)(5)(b)`'s key combinatorial input,
avoiding a bespoke induction on `4 ^ n`). -/

theorem deltaPair_fst_eq_testBit (k i : Nat) : (deltaPair k i).1 = k.testBit (2 * i) := by
  show decide ((k / 4 ^ i) % 2 = 1) = k.testBit (2 * i)
  rw [Nat.testBit_eq_decide_div_mod_eq, show (4 : Nat) ^ i = 2 ^ (2 * i) by
    rw [show (4 : Nat) = 2 ^ 2 from rfl, <- pow_mul]]

theorem deltaPair_snd_eq_testBit (k i : Nat) : (deltaPair k i).2 = k.testBit (2 * i + 1) := by
  show decide ((k / 4 ^ i / 2) % 2 = 1) = k.testBit (2 * i + 1)
  rw [Nat.div_div_eq_div_mul, Nat.testBit_eq_decide_div_mod_eq, show (4 : Nat) ^ i * 2 = 2 ^ (2
    * i + 1)
    by rw [show (4 : Nat) = 2 ^ 2 from rfl, <- pow_mul, pow_succ]]

/-- **Distinctness of bounded bit-sources**: two bit-sources both `< 4 ^ n` and unequal must
disagree (via `deltaPair`) at some position strictly below `n`. Unlike `Theorem88d.lean`'s
`eq_of_deltaOf_agree_of_lt_two_pow` (which this directly mirrors), agreement of `deltaPair k`/
`deltaPair k` on `[0, n)` means agreement of `k.testBit`/`k'.testBit` on every bit `< 2 * n`
(both
the `2 * i` and `2 * i + 1` readings) -- covering all of `testBit`'s bits below the bound `4 ^
n =
2 ^ (2 * n)`, so `Nat.eq_of_testBit_eq` still finishes in one step once every bit position is

```

```

/-! ## 8.12(d)(3)(f): disjointness across disagreeing, non-junk sign-sequences

Mirrors `Theorem88d.lean`'s `atomUCode_disjoint`. Completes 8.12(d)(3). Unlike `
atomUCode_disjoint`
(which reproves disjointness by induction at the code level, since `Theorem88d.lean`'s `U`/`D`
account has no free-standing `Set`-level disjointness fact to transfer from), here the *entire*
mathematical content is already `atomPairG_disjoint` from `(d)(1)` -- this sub-part is purely a
transfer along `(d)(3)(d)`'s `atomPairCodeState_correct`, so needs `(d)(1)`'s full hypothesis
list
(`SplitSpec` for `splitX`/`splitY`, `IsPositive`/`DiffClosed`/`Nonempty` for `D_0`/`D_1`) in
addition
to `(d)(3)`'s own computability hypotheses. -/

/--! ## 8.12(d)(4)(a): `IsComputableUnion` -- the missing "union index" prerequisite

`ComputablePresentation` (Definition 7.1) only makes **intersection** effective (`inter`/
`inter_spec`, guarded by `cons_computable`), because `NeighborhoodSystem.inter_mem` makes
intersection a *primitive* closure property of a neighbourhood system -- unlike `I`, `U` is
not
required to stay inside `V.mem` at all. `Exercise812c.lean`'s `XPseq`/`YPseq` (`(d)(4)`'s
eventual
code-level targets, `XPseqCode`/`YPseqCode`) are nonetheless *growing unions* of atoms that
Scott's
own `NoMinimal`/`SplitSpec` argument (`XPseq_mem`/`YPseq_mem`, already `Pass`) shows land back
inside `D_1.mem`/`D_0.mem` -- but only as a `Prop`-level existential (via `P.surj`), giving no
way to
*compute* the resulting index. `IsComputableUnion` supplies exactly that missing effective
witness,
mirroring `IsComputableDiff` (`(d)(3)(a)`)'s shape verbatim but for `U` instead of `I`. One
structure again serves **both** `P_0` and `P_1` symmetrically. -/

/-- **Union-closure**, the `U` analogue of `NeighborhoodSystem.DiffClosed`: the union of two
neighbourhoods is again a neighbourhood. Unlike `DiffClosed`, no "`-or-{}" branch is needed --
a
union of two `NoMinimal`-nonempty neighbourhoods is automatically itself non-empty, so the only
question `UnionClosed` settles is whether the union stays inside `V.mem`. -/
def NeighborhoodSystem.UnionClosed {a : Type*} (D : NeighborhoodSystem a) : Prop :=
  forall {X Y : Set a}, D.mem X -> D.mem Y -> D.mem (X U Y)

/-- **IsComputableUnion P**: set-union relative to the presentation `P` is computable -- a
primitive-recursive `unionIdx : Nat -> Nat -> Nat` indexing `X n U X m` whenever that
union is a genuine
neighbourhood (`unionIdx_spec`, mirroring `inter_spec`/`IsComputableDiff.diffIdx_spec` exactly)
,
together with a decider for that side-condition (`union_computable`, mirroring
`cons_computable`/`IsComputableDiff.diff_computable`). Only `unionIdx` is data; the rest are
`Prop`s, so this stays choice-free to *state* (any particular instance may of course need
`Classical.choice` to *construct*, exactly like `inter`/`cons_computable`/`IsComputableDiff`

```

```

themselves would for an arbitrary effectively-given system). -/
structure IsComputableUnion {a : Type*} {V : NeighborhoodSystem a} (P : ComputablePresentation
  V)
  where
    /-- Index of `X n U X m`, as a function of the two input indices. -/
    unionIdx : Nat -> Nat -> Nat
    /-- `unionIdx` is primitive recursive (on the `Nat.pair` coding of `n, m`). -/
    unionIdx_primrec : Nat.Primrec (fun t => unionIdx t.unpair.1 t.unpair.2)
    /-- `unionIdx n m` genuinely indexes `X n U X m` whenever that union is (exactly) some `X k`
        --
        i.e. whenever it is a genuine neighbourhood. -/
    unionIdx_spec : forall {n m : Nat}, (exists k, P.X k = P.X n U P.X m) -> P.X (unionIdx

namespace IsComputableUnion

variable {a : Type*} {V : NeighborhoodSystem a} {P : ComputablePresentation V}

/-- **Under `UnionClosed`, the existential is unconditionally true** -- every `X n U X m` is
  a
  genuine neighbourhood, hence indexed by `P.surj`. Mirrors
  `IsComputableDiff.diff_exists_iff_ne_empty`, but simpler: `U` has no "-or-empty" branch to
  rule
  out, so this is a plain existence fact rather than an `iff`. Not needed to *state*
  `IsComputableUnion` (kept off the structure itself, matching how `DiffClosed`/`UnionClosed` are
  separate hypotheses from `ComputablePresentation` elsewhere in this file); recorded here for
  convenience, though the eventual `(d)(4)(c)`/`(d)` instantiation is expected to discharge
  `unionIdx_spec`'s hypothesis directly from `XPseq_mem`/`YPseq_mem`-style facts specific to the
  atoms actually in play, rather than from a blanket `UnionClosed` on all of `D`. -/
theorem union_exists (hunion : V.UnionClosed) (n m : Nat) :
  exists k, P.X k = P.X n U P.X m :=
  P.surj (hunion (P.mem_X n) (P.mem_X m))

end IsComputableUnion

/-! ## 8.12(d)(4)(b): unions of already-genuine neighbourhoods are genuine

**Scope note (adjustment from the original `arxiv.md` scoping, discovered during execution):**
the
original scoping anticipated `XPseqG`/`YPseqG`, a classical `Set`-level generalization of
`Exercise812c.lean`'s `XPseq`/`YPseq` over abstract `splitX`/`splitY`, transcribing
`XPseq_mem`/`XPseq_zero`/`YPseq_mem`/`YPseq_zero` onto the abstracted definitions, as the
prerequisite for `(d)(4)(c)`/`(d)`'s code-level folds. On inspection this is both **unnecessary
**
and, worse, **not the right shape**: `XPseq_mem` (`Exercise812c.lean`) is proved via the heavy
`combinedX`/`combinedY`/`transfer_inter_empty_combined` detour, which exists to relate `XPseq n`
`s
*emptiness* back to `X n`'s (so as to rule out the `{}` branch of a prior dichotomy) --
machinery that
is about identifying `XPseq n` with *Scott's specific* recovered neighbourhood, not about the
bare
fact the upcoming code-level fold actually needs: that a *finite, growing union* of already-
mem`
pieces stays `mem`. That bare fact is available far more cheaply, directly from the two
hypotheses
already in scope everywhere in this file (`IsPositive`, `DiffClosed`) plus `NoMinimal`, via
`Exercise812c.lean`'s own generic `union_mem_or_empty` (proved from `IsPositive`/`DiffClosed`
alone,
**no** `NoMinimal` needed there since it only claims the *dichotomy* `= {} \ / mem`) composed

```

with one
line ruling out the $\{\}$ branch whenever both inputs are **already** known **mem** (so **already** known
non-empty, via *NoMinimal*). This lemma is **the** prerequisite $(d)(4)(c)$'s folds
actually
use to discharge *IsComputableUnion.unionIdx_spec*'s existential hypothesis at every step: each
half-step atom folded in is unconditionally *P.mem_X*-genuine (*ComputablePresentation.mem_X*
is
total, regardless of any code-level "junk" bookkeeping -- cf. *atomPairIdx0_mem*/
atomPairIdx1_mem,
 $(d)(3)(e)$), so the running union of finitely many such atoms is genuine by a one-line
induction
via this lemma, with **no** need to first relate any of it back to *XPseq*/*YPseq* or to redo
any
part of $(d)(1)$'s already-completed abstraction over *splitX*/*splitY*. -/

Lean 4 source (lines 2001–2400)

```
/-- **A union of two already-genuine neighbourhoods is again genuine** (sharper than
`union_mem_or_empty`'s bare dichotomy): under `NoMinimal`, a `mem` set is never empty
(`NoMinimal.mem_ne_empty`), so  $X \cup Y \supseteq X \neq \{\}$  rules out the dichotomy's  $\{\}$ 
branch outright. -/
theorem NeighborhoodSystem.mem_union_of_mem {α : Type*} {D : NeighborhoodSystem α}
  (hpos : D.IsPositive) (hdiff : D.DiffClosed) (hnomin : D.NoMinimal) {X Y : Set α}
  (hX : D.mem X) (hY : D.mem Y) : D.mem (X ∪ Y) :=
  (union_mem_or_empty hpos hdiff (Or.inr hX) (Or.inr hY)).resolve_left fun h =>
  hnomin.mem_ne_empty hX (Set.subset_eq_empty Set.subset_union_left h)

/-! ## 8.12(d)(4)(c): `XPseqCode` -- the code-level `X`-side union fold

Mirrors `Theorem88d.lean`'s `yFoldStep`/`yFold`/`YseqCode` (the union fold over non-junk atoms)
,
staying purely at the *code* level throughout (no reference to Exercise812c.lean's classical
`XPseq`/`atomPair`, nor even to  $(d)(1)$ 's classical atomPairG -- see  $(d)(4)(b)$ 's scope
note for
why that classical detour turned out unnecessary). Correctness (XFold_found_iff/  

XFold_mem_of_found/XFold_mem_iff) is stated *conditionally* on the fold's "found" flag
throughout, exactly mirroring yFold_found_iff/yFold_mem_iff's own phrasing; see the closing
docstring below for why the *unconditional* form at N = 4? is a flagged, deferred gap rather
than
forced through today. -/

/-- **Once "found", the running union's code is always `D_1`-genuine.** New content beyond
`Theorem88d.lean`'s precedent (there, `unionUX`'s output is unconditionally genuine, since `U`
is
unconditionally union-closed): here `hUnion1.unionIdx_spec`'s conclusion is conditional on its
existential hypothesis, discharged at each step via `(d)(4)(b)`'s `mem_union_of_mem` applied to
the
running union (genuine, by this very induction) and the new atom (genuine, `xPseqAtomIdx_mem`,
unconditionally). This is exactly the fact `XFold_mem_iff` below needs to legally rewrite
through
`unionIdx_spec` at its own inductive step. -/

/-- **8.12(d)(4)(d)(v): the converse-biconditional, `D_1`-side.** The `D_1`-side mirror of
`atomPairG_fst_eq_empty_of_junk_eq_one` -- but **not** a naive `.1` <-> `.2` transcription: the
two
per-step sub-cases' roles *swap* relative to the `D_0`-side proof. A junk state at depth `n +
1`
either (i) was already junk at depth `n` (propagated forward via `atomPairG_snd_subset`), or
(ii) freshly created this step, splitting on the exact same `xcheck`/`ycheck` decomposition
(`selectFn xcheck 1 ycheck = 1`, tied to `P_0`/`A1` and `P_1`/`B2` respectively, shared
verbatim with
the `D_0`-side proof -- the underlying per-step algebra doesn't know which side we're targeting
):
**`xcheck = 0`** (`X`-sub-step non-junk) -- the `Y`-sub-step's own direct-refine check* trips
the
`D_1`-side (`B2`) *directly*, and since `B2` **is** this branch's target, **no
`atomPairG_invariant` hop is needed** (unlike the `D_0`-side proof, where this same branch's
direct
trigger is `B2` but the target is `A2`, needing the invariant to hop across). **`xcheck = 1`**
(`X`-sub-step's own check trips) -- this gives `A1 = {}` directly (identical derivation to the
`D_0`-side proof), but now the target `B2` needs a hop *from* `A1` *to* `B1` via `xStepG_spec`'
s own
half-step biconditional `hspecAB` (not the depth-crossing `atomPairG_invariant` -- this is a
purely
local one-step fact, already in scope), then propagates via the *trivial* `yStepG_snd_subset` (
no
`SplitSpec` hypotheses needed at all) rather than the `D_0`-side's `SplitSpec`-needing
`yStepG_fst_subset`. Net effect: this `D_1`-side proof needs `atomPairG_invariant` in *neither*
branch, genuinely simpler than `(c)(v)`'s own proof. -/

/-! ### 8.12(d)(4)(c)(vi): assembling the unconditional "found" fact

`Theorem88d.lean` discharges its own analogous conditional hypothesis unconditionally via
`exists_atomUEmpty_zero`/`yFold_two_pow_found`, using structure specific to that one-sided
embedding (`idxSet (e P)`, `self_mem_idxSet`) that has no analogue here. For this two-sided
construction, "`exists i < 4?, xPseqAtomJunk n i = 0`" needs, classically, some `i` with the

```

```

depth-`n`
state non-junk *and* its `D_0`-side specifically intersecting `P_0.X n` non-trivially -- i.e.
an
analogue of `Exercise812c.lean`'s `XPseq_ne_empty`, which is there proved via the heavy
`combinedX`/`combinedY`/`transfer_inter_empty_combined` detour (the same machinery `(d)(4)(b)`'
s
scope note found unnecessary for the *conditional* correctness above).

**Both classical and converse-biconditional halves were already done** `(d)(4)(c)`'s nested
sub-goals `(c)(i)`-`(c)(v)`, all `Pass`: by induction on `n`, the classical `atomPairG`-pieces
cover `D_0.master` (`atomPairG_master_covered`/`atomPairG_master_covered_deltaPair`), giving
`exists_atomPairG_deltaPair_inter_Xn_ne_empty` -- some bit-source `i < 4?` whose depth-`n` `D_0`
-side
intersects `P_0.X n` non-trivially, purely classically `(c)(i)`-`(c)(iv)`. `(c)(v)`'s
`atomPairJunk_eq_zero_of_ne_empty` supplies exactly the missing converse half of
`(d)(3)(d)`'s `atomPairCodeState_correct` needed to transport this non-emptiness witness back
to
the code level: since `(atomPairG ... n).1 I P_0.X n != {}` forces `(atomPairG ... n).1 !=
{}`, it
forces `atomPairJunk n i = 0` (i.e. `xPseqAtomJunk n i = 0`, `atomPairJunk_eq_zero_of_ne_empty`
),
discharging `XFold_found_iff`'s hypothesis at exactly the witness `i` from
`exists_atomPairG_deltaPair_inter_Xn_ne_empty`.

**This section `(c)(vi)` is the final assembly**, chaining those two facts exactly as planned
:
`xPseqAtomJunk_exists_zero` is the unconditional "found" existential itself; `
XFold_four_pow_found`
transports it through `XFold_found_iff` to the fold's own found flag at `N = 4?`
(mirroring `Theorem88d.lean`'s `yFold_two_pow_found`); and `XPseqCode_mem_unconditional`/
`mem_XPseqCode_iff_unconditional` re-specialize `XPseqCode_mem`/`mem_XPseqCode_iff` at that
unconditional witness, dropping the `hfound` hypothesis entirely. This closes `(d)(4)(c)` in
full
(all of `(c)(i)`-`(c)(vi)` now `Pass`, unconditionally). -/

/-! ## 8.12(d)(4)(d): `YPseqCode`, the code-level `Y`-side union fold

Symmetric to `(d)(4)(c)`'s `XPseqCode`, but genuinely harder in one respect (matching
`Exercise812c.lean`'s own `YPseq` docstring): `ySubStep`'s inputs already depend on position `n`
`s
own `X`-sub-step bit, so the half-step atom needs an *extra* free bit `bx`, and the resulting
fold
is a union over *two* indices (`i < 4?` and `bx in {0,1}`), not one. Rather than combine `i`
`/`bx`
into a single `2*4?`-element fold, this is built as an **outer `2`-way union of two inner `4?`-
folds**
(`YFoldInner n 0 _`, `YFoldInner n 1 _`, one per literal value of `bx`) via a new, reusable
`combineFound2` helper -- simpler than threading `bx` through the recursion state itself, since
`Nat.Primrec.prec` already needs `n` held fixed as its own outer parameter, and pairing `bx`
alongside it costs nothing. -/

/-- **Combine two `(found, code)` packed fold results into one**: union their codes via `hUnion`
when both found something, and simply propagate whichever single side found something otherwise
(mirroring `XFoldStep`/`YFoldStep`'s own "skip junk, else union" shape one level up). Generic
in any
`IsComputableUnion`, reused below for `YPseqCode`'s "outer 2-way union" of its two `bx`-fixed
inner
folds. -/

/-! ## 8.12(d)(4)(d)(vi): `YPseqCode`'s "found" flag is unconditionally `1`

```

Mirrors `XPseqCodeUnconditional`, but doubled over `bx`. The extra wrinkle beyond `(c)(vi)`'s template: `(d)(iv)`'s covering fact `(exists\_atomPairG\_deltaPair\_inter\_Yn\_ne\_empty)` only pins down a non-trivial intersection of `B := (atomPairG (deltaPair i) n).2` itself with `P\_1.X n` -- *before* any half-step -- whereas `yPseqAtomJunk n i bx = 0`'s witnessing genuinely needs a non-trivial intersection of `B`'s **half-step-`bx` split piece** `(xStepG splitX A B (P\_0.X n) bx).2` with `P\_1.X n`. The bridge: `xStepG\_snd\_union` `(d)(i)` says these two split pieces `(bx = true`/`false)` reunion to exactly `B`, so `B I P\_1.X n != {}` forces *at least one* of them to

```

    meet `P_1.X n`
non-trivially (a `Set.union_inter_distrib_right` chase) -- no need to know *which* `bx` in
    advance,
matching `arxiv.md`'s own scoping prediction exactly. -/

/-- **The half-step-`bx` atom is non-junk, given the classical split piece meets `P_1.X n`.**
The
one-bit-generic engine behind `yPseqAtomJunk_exists_zero`: given the incoming depth-`n` state
is
non-junk (`hjunk0`) and, for a *chosen* bit `b`, both the direct-refine piece `A1(b) != {}`
(`hne`)
and the split piece meets `P_1.X n` non-trivially (`hinter`), the half-step atom
`yPseqAtomJunk n i` (if b then 1 else 0) is `0`. Chases `xSubStep`'s own junk formula down to
`emptyInterDec`/`emptyDiffDec` (`P_0`-side, from `hne` via `atomPairCodeState_correct`'s
forward
identification) to get `xSubStep`'s output non-junk, then `xSubStep_correct` to identify its
`D_1`-side index with the classical split piece, then the same `emptyInterDec` reading (`P_1`-
side,
from `hinter`) collapses `ySubStep`'s own forced-`"+`" junk check to `0`. -/

/ -! ## 8.12(d)(5)(a): zero/master facts for `XPseqCode`/`YPseqCode`

Generalizes `Exercise812c.lean`'s `XPseq_zero`/`YPseq_zero` to the code level: given Scott's
zero-convention `hX0 : P_0.X 0 = D_0.master`/`hY0 : P_1.X 0 = D_1.master` (the code-level
analogue of
`(c)(vii)`'s own `hX0`/`hY0`), `P_1.X (XPseqCode ... 0) = D_1.master` and `P_0.X (YPseqCode ...
0) =
D_0.master`.

Both proofs need only the depth-`0` slice of the fold: `4 ^ 0 = 1` forces the existential
witness
`i` in `mem_XPseqCode_iff_unconditional`/`mem_YPseqCode_iff_unconditional` to be `0`, `
atomPairG`'s
own `n = 0` base clause is `(D_0.master, D_1.master)` regardless of sign-history
(`atomPairCodeState_correct`'s zero case, unconditionally non-junk via the new `
atomPairJunk_zero`),
and the `*same*` `SplitSpec` argument `XPseq_zero`/`YPseq_zero` use -- the "?"-branch forced
empty by
`A \ Xn = D_0.master \ D_0.master = {}` (resp. `D_1`-side), pinning the "+"-branch to the full
union via
`(split A B Xn).1 U (split A B Xn).2 = B` -- transports through `IsComputableSplit`.
posIdx_spec`
verbatim. The `subseq D_1.master`/`subseq D_0.master` half of each equality needs no
case analysis at all: every
half-step atom is `mem`-genuine unconditionally (`xPseqAtomIdx_mem`/`yPseqAtomIdx_mem`), hence
`subseq D_1.master`/`D_0.master` via `sub_master` regardless of which bit-source/junk-
status witnessed it.

The `Y`-side reuses the `X`-side computation directly: `yPseqAtomState`'s inner `xSubStep` call
at
bit `bx = 1` is *definitionally* `xPseqAtomState` (identical packed arguments), so the `D_1`-
side
value already computed for `XPseqCode`'s zero fact doubles as the "`B`"-input the `Y`-sub-step`
s
own split (`hSplitY`) needs -- only the `D_0`-direct-refine companion value (`xPseqAtomIdx0_eq
`, the
`stateIdx0` twin of `xPseqAtomIdx_eq`) is new content. -/

/-! ## 8.12(d)(5)(b)(i): the `X`-side I-formula for `XPseqCode`

**Design decision (resolved, after a bounded search per `(d)(5)`'s own flagged decision):** `(d)
(5)(b)`'s
order/intersection transfer facts (`X_subset_iff_XPseqCode_subset` etc.) compare `P_0.X i`/`P_0
.X j` --
*raw*, mutually unrelated enumeration indices, not outputs of any `atomPairG` recursion -- so
no
shortcut bypassing `Exercise812c.lean`'s `combinedX`/`combinedY`/`genAtom`-interleaving
apparatus
(**Route 1**) was found: relating two *arbitrary* indices intrinsically needs the "embed both
families
into one recursive tree" trick that apparatus provides, exactly as `(d)(5)`'s finding 2
anticipated.
**However, a genuine, non-trivial simplification survives** in the one piece of that apparatus
that
*is* code-native: the "I-formula" identities (`xStep_snd_eq_inter_XPseq`/`
yStep_fst_eq_inter_YPseq`,
`Exercise812c.lean` lines 899-1172, ~270 lines total) needed to seed the interleaved family's
odd-depth

```

half-steps. Classically these need heavy case analysis because `XPseq`/`YPseq` are unions over the
the
uncountable `?' : Nat -> Bool x Bool`. At the code level, `XPseqCode`/`YPseqCode` are already unions
over *at most* `4 ?` literally distinct* bit-sources (`mem\_XPseqCode\_iff\_unconditional`/`mem\_YPseqCode\_iff\_unconditional`, `(d)(4)`, already `Pass`), and any two distinct bit-sources both
`< 4 ?` are *automatically* distinguished by some `deltaPair`-digit ` $< n`
(`exists_deltaPair_ne_of_lt_of_ne` above) -- no "history agrees through `n`" case ever arises, so the
`subseteq` direction collapses to a single disjointness appeal (`atomPairCodeState_disjoint`) instead of a
?-indexed case split. This sub-part builds the `X`-side instance of that shortened I-formula; `(d)(5)(b)(ii)` will build the (structurally harder, extra-`bx`) `Y`-side instance, then `(d)(5)(b)(iii)`
assembles the generalized `combinedXCode`/`combinedYCode`/`hcore` machinery these feed, reusing `Theorem88.lean`'s `transfer_dir`/`genAtom` apparatus (already fully generic, no changes needed) for
the final headline theorems. -/$

/--! ## 8.12(d)(5)(b)(ii): the `Y`-side I-formula for `YPseqCode`

The code-level analogue of `Exercise812c.lean`'s `yStepfst_eq_inter_YPseq`, needed to seed
`(b)(iii)`'s `combinedXCode`'s odd-depth half-step. Structurally harder than `(b)(i)` exactly
as
anticipated: `yPseqAtomIdx n i bx` carries a *free* extra bit `bx`, so both the closed form and
the
disjointness argument need an extra case split on `bx` in addition to `i`. -/

/-! ## 8.12(d)(5)(b)(iii): `combinedXCode`/`combinedYCode`/`combined?`, and `hcore`

The generalized interleaved-family machinery, mirroring `Exercise812c.lean`'s `combinedX`/`combinedY`/`combined?` (lines 1236-1457) with `atomPair -> atomPairG`, `splitChoice` -> `splitX`/`splitY`, `XPseq k -> P\_1.X (XPseqCode ... k)`, `YPseq k -> P\_0.X (YPseqCode ... k)`. **`combined?`/`deinterleave?` need no code-level replica at all*: both are already pure functions of `Nat -> Bool x Bool`/`Nat -> Bool` and `Nat`, with no dependence whatsoever on `X`/`Y`/`D\_0`/`D\_1`, so `Exercise812c.lean`'s versions (and their `\_even`/`\_odd`/`combined?\_deinterleave?` lemmas) are reused completely verbatim below -- only `combinedXCode`/`combinedYCode` themselves are new.

The genuinely new content is the two "two-branch closed form" lemmas (``xStepG_snd_succ_eq_XPseqCode`/`yStepGfst_succ_eq_YPseqCode``), generalizing ``(b)(i)`/`(b)(ii)``'s bounded-existential I-formulas (stated only for bit-sources ``k < 4 ^ n``) to `*arbitrary*` ``? : Nat -> Bool x Bool``, via ``encodeDeltaPair ? n`` (``(d)(4)(c)(iii)``, already ``Pass``) as the bounded representative. Two genuinely new sub-cases appear along the way that neither ``(b)(i)`` nor ``(b)(ii)`` needed: (1) ``(atomPairG ... ? n)``'s component may be ``{}`` for an arbitrary ``?`` (impossible for the ``XPseqCode`/`YPseqCode`` folds' own witnesses, which are always non-junk by construction) -- handled directly via ``SplitSpec`` alone, no code/junk facts needed; (2) even when non-``{}``, the `*fresh*` half-step atom itself (``xPseqAtomJunk`/`yPseqAtomJunk``) may independently be junk -- handled by a "junk-mismatch" trick: ``mem_XPseqCode_iff_unconditional`/`mem_YPseqCode_iff_unconditional``'s existential witnesses are `*guaranteed*` non-junk, so a junk target automatically differs from every witness, collapsing straight to the same disjointness apparatus ``(b)(i)`/`(b)(ii)`` already built. -/

/-- **The `X`-side I-formula, generalized to an arbitrary `?`** (not just a bounded bit-source
`k <
4 ^ n`): the `X`-sub-step's own `"+"/`true` branch, run on `atomPairG`'s depth-`n` component
for
*any* history `?`, is exactly the intersection of that component's `D_1`-side with `XPseqCode n`
`.
Bridges `(b)(i)`'s bounded-existential `xPseqAtomIdx_eq_inter_XPseqCode` up to the fully
general
statement `Exercise812c.lean`'s own `xStep_snd_eq_inter_XPseq` makes, via `encodeDeltaPair ? n`
as
the bounded representative: if the represented component is already `{}`, both sides are `{}`
directly from `SplitSpec`; otherwise `(d)(4)(c)(v)`'s `atomPairJunk_eq_zero_of_snd_ne_empty`
gives
a non-junk bit-source to feed `(b)(i)`'s headline, *unless* the fresh half-step atom is itself
junk
-- handled by the "junk-mismatch" trick documented at the section level. -/

/-- **The `Y`-side I-formula, generalized to an arbitrary `?`** (not just a bounded bit-source
`k < 4 ^ n`) **and a free `bx : Bool`** (not just the bit `? n`.1` itself, matching
`Exercise812c.lean`'s own `yStepfst_eq_inter_YPseq`): the `Y`-sub-step's `"+"/`true` branch,
run
on `xStepG`'s own output at `any* bit `bx` and `any* history `?`, is exactly the intersection
of
that output's `D_0`-side with `YPseqCode n`. Same overall strategy as
`xStepG_snd_eq_inter_YPseqCode`: encode `?`'s depth-`n` prefix as `k := encodeDeltaPair ? n`,
handle
`A1 = {}` directly via `SplitSpec`, and otherwise split on `yPseqAtomJunk n k` (if `bx` then 1
else 0)`
-- zero feeds `(b)(ii)`'s headline (after bridging its `yPseqAtomIdx` back to the `yStepG`-
level via
`xSubStep_correct`/`ySubStep_correct`, mirroring `yPseqAtomIdx_subset_xStepGfst`'s own internal
`hgoaleq`); one is "fresh junk" at `this*` extra half-step, handled by first showing the `X`-sub
-step
itself must still be non-junk (else `A1 = {}`, contradicting the case hypothesis), so the
freshness
must come from the `Y`-sub-step's own direct-refine check, giving `B1 I Yn = {}` and hence
the goal's
`true`-branch output is `{}` directly; the `I YPseqCode` side is then `{}` via the same
"junk-mismatch" disjointness trick as the `X`-side, now with an extra case split on the witness
's
own `bx`-bit (`xStepG_disjoint_of_ne` when the bit differs at the same `k`, else
`atomPairCodeState_disjoint` as before). -/

/-! ### Exercise 8.12(d)(5)(b)(iv): the headline transfer theorems

Instantiates `Theorem88.lean`'s fully generic `transfer_dir` with `Z1 := combinedXCode`,
`M1 := D_0.master`, `Z2 := combinedYCode`, `M2 := D_1.master`, and `(b)(iii)`'s `hcoreCode`,
transcribing `Exercise812c.lean`'s own `transfer_empty_combined`/`transfer_subset_combined`/
`transfer_double_subset_combined`/`transfer_inter_eq_combined` wrappers one-for-one with
`combinedX` |-> `combinedXCode`, `combinedY` |-> `combinedYCode`, `hcore` |-> `hcoreCode`. The
headline
deliverable then specializes each even/even and odd/odd index pair back down to plain
statements
about `P_0.X`/`XPseqCode` and `YPseqCode`/`P_1.X`, discharging the `I master` bookkeeping
with
`D_0.sub_master`/`D_1.sub_master` applied to `P_0.mem_X`/`P_1.mem_X` directly -- a genuine
simplification over `Exercise812c.lean`'s own proof: since every value of `combinedXCode`/
`combinedYCode` is literally `P_0.X`_/`P_1.X`_ for some index, no separate `

```

```

    XPseq_subset_master`/
`YPseq_subset_master`-style theorem is needed, `ComputablePresentation.mem_X` already covers
every
case (even or odd) uniformly. -/

/#!/ ### Exercise 8.12(d)(5)(c): cross-family order and equality facts

Generalizes `Exercise812c.lean`'s `X_subset_YPseq_iff_XPseq_subset_Y`/
`YPseq_subset_X_iff_Y_subset_XPseq`/`XPseq_eq_Y_iff_X_eq_YPseq` ((c)(vii)(3)/(4)) to the code
level. Needs no new proof machinery beyond `(d)(5)(b)`'s transfer facts -- each is a direct
specialization of `transfer_subset_combinedCode` at *mixed* even/odd (resp. odd/even) index
pairs. -/

```

```

analogue
of `Exercise812c.lean`'s `toD1.up_mem`, but needing only one `surj` call (not two): `P_1.
surj`
names the arbitrary target `T2` as some `P_1.X k`; `(d)(5)(c)(i)`'s cross-parity order fact
then
transports `x.mem (P_0.X i)` across to `x.mem (P_0.X (YPseqCode ... k))` -- already literally
`x.mem (P_0.X j)` for the explicit witness `j := YPseqCode ... k`, no further covering search
needed;
`(d)(5)(c)(iii)`'s `XPseqCode_eq_Y_iff_X_eq_YPseqCode`, applied at the self-referential pair
`(YPseqCode ... k, k)` whose "other side" is `rfl`, supplies the closing index equation for
free. -/

    hUnion0
  hUnion1 hX0 in
/-- **Exercise 8.12(d)(5)(d)(ii).** `toD1Code : D_0.Element -> D_1.Element`, the code-level
  pushforward
  filter `{T | exists n, T = P_1.X (XPseqCode ... n) /\ x.mem (P_0.X n)}` -- generalizes `
    Exercise812c.lean`'s
  `toD1` ((c)(vii)(4)). `sub` cites `(d)(4)`'s `XPseqCode_mem_unconditional` directly; `
    master_mem`
  cites `(d)(5)(a)`'s `XPseqCode_zero` at the witness `n = 0`, using `hX0` to identify `P_0.X 0`
    with
  `D_0.master`. `inter_mem` needs **no** covering search (unlike `toD1`'s `exists_inter_index_X`):
    :
  given `hxi : x.mem (P_0.X i)`/`hxj : x.mem (P_0.X j)`, `x.inter_mem hxi hxj`/`x.sub` shows
  `P_0.X i I P_0.X j` is already `D_0`-genuine, so `P_0.surj` names it as some `P_0.X m`
    outright,
  `P_0.inter_spec` reads this off as the closed-form index equation `P_0.X (P_0.inter i j) = P_0.
    X i I
  P_0.X j`, and `(d)(5)(b)(iv)`'s `X_inter_eq_iff_XPseqCode_inter_eq` transports the same
    equation
  across to `XPseqCode`, so `P_0.inter i j` is directly the witness index needed. `up_mem` is
    exactly
  `(d)(5)(d)(i)`'s `toD1Code_up_mem`. -/

predicate `fun S => exists n, S = P_0.X (YPseqCode ... n) /\ y.mem (P_1.X n)`, the exact
mirror of
`(d)(5)(d)(i)`'s `toD1Code_up_mem` for the `D_1 -> D_0` direction: destructure `h1` as `i,
rfl, hyi>`;
`P_0.surj` names the arbitrary target `S2` as some `P_0.X k`; `(d)(5)(c)(ii)`'s
`YPseqCode_subset_X_iff_Y_subset_XPseqCode` turns `hS1S2 : P_0.X (YPseqCode ... i) subseq
P_0.X k` into
`P_1.X i subseq P_1.X (XPseqCode ... k)`; `y.up_mem hyi (XPseqCode_mem_unconditional k)
this` gives
`y.mem (P_1.X (XPseqCode ... k))` -- already literally `y.mem (P_1.X j)` for the explicit
witness
`j := XPseqCode ... k`, no covering search needed; `(d)(5)(c)(iii)`'s
`XPseqCode_eq_Y_iff_X_eq_YPseqCode`, applied at the self-referential pair `(k, XPseqCode ... k)
whose "other side" is `rfl`, supplies the closing index equation `P_0.X k = P_0.X (YPseqCode
...
(XPseqCode ... k))` for free -- note no `.symm` is needed here, unlike `toD1Code_up_mem`, since
the
goal orientation already matches `XPseqCode_eq_Y_iff_X_eq_YPseqCode`'s `.mp` output directly.

/-- **Exercise 8.12(d)(5)(d)(iv).** `toD0Code : D_1.Element → D_0.Element`, the code-level
pullback
filter `{S | exists n, S = P_0.X (YPseqCode ... n) /\ y.mem (P_1.X n)}` -- exact mirror of
`(d)(5)(d)(ii)`'s
`toD1Code` for the `D_1 → D_0` direction. `sub` cites `(d)(4)`'s `
YPseqCode_mem_unconditional`
directly; `master_mem` cites `(d)(5)(a)`'s `YPseqCode_zero` at the witness `n = 0`, using `hY0`
to
identify `P_1.X 0` with `D_1.master`. `inter_mem` mirrors `toD1Code`'s corrected version
exactly, with
the roles of `P_0`/`P_1` swapped: given `hyi : y.mem (P_1.X i)`/`hyj : y.mem (P_1.X j)`, `y.
inter_mem`/
`y.sub` shows `P_1.X i I P_1.X j` is already `D_1`-genuine, so `P_1.surj` names it as some `
P_1.X m`
outright, `P_1.inter_spec` reads this off as the closed-form index equation `P_1.X (P_1.inter i
j) =
P_1.X i I P_1.X j`, and `(d)(5)(b)(iv)`'s `YPseqCode_inter_eq_iff_Y_inter_eq` transports the
same
equation across to `YPseqCode`, so `P_1.inter i j` is directly the witness index needed (**note
the
iff's orientation is reversed relative to `X_inter_eq_iff_XPseqCode_inter_eq`**: `YPseqCode`-
stuff is
on the *left*, so this uses `.mpr` with `hinterEq.symm`, not `.mp` with `hinterEq` as `toD1Code
`
did). `up_mem` is exactly `(d)(5)(d)(iii)`'s `toD0Code_up_mem`. -/

/-- **Exercise 8.12(d)(5)(e)(iv), final assembly.** The order isomorphism `D_0.Element ?o
D_1.Element`, generalizing `Exercise812c.lean`'s `domainIso812c` ((c)(vii)(6)) to the code
level.
`toFun`/`invFun`/`left_inv`/`right_inv` are direct citations of `(d)(5)(d)`'s `toD1Code`/`
toD0Code`
and `(e)(ii)`/`(e)(iii)`'s `toD0Code_toD1Code`/`toD1Code_toD0Code`. `map_rel_iff` is a direct
transcription of `domainIso812c.map_rel_iff` (lines 2094-2108), substituting the code-level
apparatus throughout: the easy `mpr` direction (`x <= x2 -> toD1Code x <= toD1Code x2`)

```

```

    is pure
unfolding, no search; the harder `mp` direction (`toD1Code x <= toD1Code x2 -> x <= x2`)
    needs only
*one* `P_0.surj` call (replacing `hXcover`, `subst`-ing the target `S` as some `P_0.X n`
    directly)
plus `(e)(i)`'s `X_eq_iff_XPseqCode_eq` to transport the resulting `XPseqCode`-index equality
    back
to `P_0.X`-coordinates -- confirming the same "no covering search" simplification found
    throughout
`(d)(5)` . -/

/-- **Exercise 8.12(d)(5)(f)(ii).** `ofIso domainIsoCode812d` is computable relative to `P_0`/`
P_1`:
via `(f)(i)`'s `toD1Code_rel_iff`, `IsComputableMap P_0 P_1 (ofIso domainIsoCode812d)` reduces
to
`REPred_2 (fun n m => exists k, P_1.X m = P_1.X (XPseqCode ... k) /\ P_0.X n subseq P_0.
X k)`. Unlike
`Theorem88n.lean`'s `isoInj_isComputableMap` (whose `eIdx` supplies a *unique* witness, no
genuine
existential), the `exists k` here is unbounded, so this mirrors `Definition72.lean`'s
`comp_isComputable`/`apply_isComputableElement` existential-closure recipe instead: the two
conjuncts are separately `RecDecidable` (`P_1.eq_computable` reindexed along the primitive-
recursive
`XPseqCode` in the first coordinate; `P_0.incl_computable` reindexed directly), conjoined
(`RecDecidable.and`), lifted to `REPred` (`.re`), and closed by `REPred.proj` over the outer
`exists k`. -/

# Exercise 8.12(e) (Scott 1981, PRG-19, Lecture VIII) -- `U` satisfies the extension property
relative to `V`

## 8.12(e)(a): the split's contract, as Lean declarations

`(d)`'s `IsComputableSplit P Q split` structure only ever gets consumed, downstream, through
its

```

```

two index functions `posIdx`/`negIdx` : Nat -> Nat -> Nat -> Nat` (`xSubStep`/`ySubStep`,
`Exercise812d.lean`).
This section fixes the *design* for those two functions concretely, as genuine `Nat`-valued `
def`s
(no proof obligations yet -- those are `(e)(c)`'s job): given a proper presentation `P` (with
an
`IsComputableDiff` witness) and a target presentation `Q` equipped with a computable canonical
bisection (`ComputableBisection`, below), decide via the proper's own `emptyInterDec`/`
emptyDiffDec`
deciders ((d)(2)) whether the "chosen branch" is (as far as these two deciders can tell) forced
empty, and fall back to the bisection only when neither decider fires.

Both `posIdxFromBisection`/`negIdxFromBisection` share the same outer shape and, not entirely
obviously, the same "either decider fires" branch value `m` (i.e. literally `B` itself) -- one
of the
two decider branches is the *genuinely correct* value in that case (`A` subseq Xn` resp. `Xn
I A = {}`
forces the corresponding piece to be exactly `B`), the other is a harmless placeholder that
later
gets junk-masked (`xSubStep`'s `newJunk`) before ever being read -- see the `(e)(a)` row of
`arxiv.md` for the case-by-case argument. Only the "both deciders silent" branch genuinely
bisects
`B`, via the supplied `ComputableBisection`. -/

namespace Scott1980.Neighborhood

open Domain.Recursive

/-- **A computable canonical bisection of a `ComputablePresentation`'s own neighbourhoods**:
two
`Nat.Primrec` index functions `left`/`right` such that `Q.X (left k)`/`Q.X (right k)` are
always
disjoint and reunite to `Q.X k`. (Nonemptiness of both pieces is *not* required here -- for the
concrete `U`/`V` instances this file eventually builds `(e)(b)`/`SplitU.lean`), it is
automatic
from `mem -> Set.Nonempty`, so is proved separately rather than carried as a field.)

**`left_congr`/`right_congr`** are a well-definedness requirement discovered while scoping `(e)
(c)`
(2026-07-05), *not* present in the earlier `arxiv.md` draft of this structure: `
ComputablePresentation.X`
is generally many-to-one (distinct raw indices `k`, `k'` can present the *same* set `Q.X k = Q.
X k'`),
so building a genuine classical `split : Set a -> Set ? -> Set a -> Set ? x Set ?` *
function of sets*
out of an index-level `left`/`right` needs `left`/`right`'s *output sets* -- not necessarily
the raw
output indices themselves -- to only depend on `Q.X k` as a set, or `(e)(c)`'s `posIdx_spec`/
`negIdx_spec` obligations (stated `forall n m k`, not just for one fixed representative) would
not be
provable. Satisfied by any canonicalizing construction (e.g. `SplitU.lean`'s `splitULeft`/
`splitURight`, built via `canonCode`, which already collapses every representative of a given
set to
one canonical index) -- expected free for both `(e)(b)`'s `SplitV.lean` and `(f)(a)`'s reuse of
`SplitU.lean`, but must be checked (or reduced to an existing `canonCode`/`canonIdx`-invariance
lemma)
when those are actually built, not merely assumed. -/
structure ComputableBisection {? : Type*} {W : NeighborhoodSystem ?} (Q :

/#!/ ### 8.12(e)(c)(ii): `splitFromBisection` and `isComputableSplit_ofBisection`

The actual classical split, and its `IsComputableSplit` proof, completing `8.12(e)(c)`.
Genuinely
new work beyond `(e)(c)(i)`: the two index functions' *joint* primitive-recursiveness (as a
single
function of the packed triple `Nat.pair n (Nat.pair m k)`, `IsComputableSplit`'s own convention
) was
not yet proved -- `posIdxFromBisection`/`negIdxFromBisection` are primitive recursive in each
*argument* separately (from their own defining pieces) but had not yet been packaged as one
triple-argument `Nat.Primrec` witness. **Deviation from the `arxiv.md` draft signature**:
`splitFromBisection` itself takes only `P`, `hDiff`, `B` (not `hpos`/`hnomin`/`hdiffClosed`) --
those
three hypotheses are needed only for *correctness* (`isComputableSplit_ofBisection`'s `
posIdx_spec`/
`negIdx_spec`, via `(e)(c)(i)`'s congruence lemmas), never for the definition itself, mirroring
how
`posIdxFromBisection`/`negIdxFromBisection` are themselves already hypothesis-free to *define*.
-/

open scoped Classical in
/-- **The classical split, built from a `ComputableBisection`: fall back to the proper-side
deciders `(d)(2)`'s `emptyInterDec`/`emptyDiffDec` whenever the input triple presents as `(P.
X n,
Q.X m, P.X k)` for some indices, and to the abstract choice-based `splitChoice` (`Exercise812c
.lean`)
otherwise. **Redesigned 2026-07-06 (repairing `8.12(g)(3)`): the *original* design (below,
kept for
the record) always returned `(Q.X (posIdxFromBisection ...), Q.X (negIdxFromBisection ...))` --
literally
never `{}` -- on the presented branch, which is jointly unsatisfiable with `SplitSpec` (see
`Exercise812d.lean`'s `IsComputableSplit.posIdx_spec` docstring for the full argument). The fix
:
route the *set-level* value through the same two deciders `posIdxFromBisection`/
`negIdxFromBisection` already consult, but let the two "one decider fires" branches produce the
literal `{}`/`B` pair directly (matching what `SplitSpec` demands: `A I Xn = {}` forces `.1
= {}` and
gives `.2` all of `B`, symmetrically for `A \ Xn = {}`), only falling through to the genuine
bisection `(B.left`/`B.right)` when *neither* decider fires (the case `exists_split` itself
needs
`E.NoMinimal` to bisect `B` into two nonempty halves). `posIdxFromBisection`/
negIdxFromBisection`
themselves need **no** change: they already compute exactly the right *index* in the "genuinely
nonempty" branch of each field and an unread junk placeholder (`m`) in the "should be `{}`"
branch --
the bug was purely in `splitFromBisection` wrapping *both* branches in `Q.X (?)`, which can
never
literally be `{}`. Also generalizes the previous "not presented -> junk `(B', B')`" fallback
(wrong in
general -- `.1 I .2 = B' I B' = B'`, not `{}`, unless `B' = {}`) to the always-correct `
splitChoice`,
needed for `SplitSpec` to hold on *every* `A`/`Xn`, not just presented ones `(e)(c)`'s own
`posIdx_spec`/`negIdx_spec` only ever constrain the presented case, so this choice of fallback
is
free to fix without touching `IsComputableSplit`'s side at all). -/
noncomputable def splitFromBisection (A : Set a) (B' : Set ?) (Xn : Set a) : Set ? x Set ? :=

simp [negIdxFromBisection, h1', h2']

/-- **`splitFromBisection` satisfies `SplitSpec`**, completing the concrete-construction half
of
`8.12(g)(3)`. Needs one extra hypothesis beyond `isComputableSplit_ofBisection`'s own,
`hQne : forall j, Q.X j != {}` -- true for both `U`/`V` (every `ComputablePresentation`
index is `mem`-
genuine, and both systems' `mem` structurally excludes `{}`; see `Exercise812.lean` line 199/
`Definition87.lean` line 96) but not derivable from `ComputableBisection`'s abstract fields
alone
(nothing there stops `Q.X (B.left m)`, say, from being `{}` in general -- only used in the "
neither
decider fires" branch, to show the bisection's two halves are each individually `!= {}`,
matching that
branch's `A I Xn != {} <-> .1 != {}`/`A \ Xn != {} <-> .2 != {}` obligations).
The two decider-fires branches
need no such hypothesis at all -- `.1`/`.2` there are literally `{}`/`B'`, and the requisite `
<-> `s
reduce to `hAB` via the algebraic facts `A I Xn = {} -> A \ Xn = A` (resp. `A \ Xn = {} ->
A I Xn = A`).
The "not presented" branch reduces to exactly `splitChoice`_isSplitSpec` (`Exercise812c.lean`),
verbatim. -/

# Exercise 8.12(e)(d)(iii) (Scott 1981, PRG-19, Lecture VIII) -- package as `
    ComputableBisection`;
instantiate for `U` <-> `V`

The exercise's literal target, given `(e)(d)(i)`-`(ii)`: a concrete `splitX812e : Set ? ->
    Set Nat ->
Set ? -> Set Nat x Set Nat` satisfying `IsComputableSplit UComputablePresentation
VComputablePresentation splitX812e`.

## A gap found while assembling this (not present in the earlier scoping): `U`'s missing
`IsComputableDiff` witness

`(e)(d)`'s own `arxiv.md` draft signature -- `splitFromBisection UComputablePresentation (U's
`IsComputableDiff`) B812e` -- assumed an `IsComputableDiff UComputablePresentation` instance
    already
existed somewhere in the codebase. It does not: grep-confirmed, `IsComputableDiff` (`
    Exercise812d.lean`,
`(d)(3)(a)` has never been instantiated for either `U` or `V`. Building it is, however,
    genuinely
mechanical -- not a new mathematical gap like `(e)(d)(i)`-`(ii)`'s -- since `IntervalPrimrec.
    lean`
already supplies every raw piece unconditionally: `diffCode`/`primrec_diffCode` (the code-
    level
set-difference primitive) and `presentedIntervals_decodeQPairList_diffCode` (its correctness,
    unconditional -- no case split on emptiness needed, unlike `combineCode`'s consistency side of
    the
story). `Udiff`/`Udiff_primrec`/`Udiff_spec`/`U_diff_computable` below are a direct structural
    mirror
of `UComputablePresentation.lean`'s own `Uinter`/`Uinter_primrec`/`Uinter_spec`/`
    U_cons_computable`,
substituting `diffCode` for `combineCode` and `U_diff_mem` (`Exercise812c.lean`, already `Pass
    `) for
`U`'s `IsPositive` as the "always mem-or-{" fact driving the decidability reduction.

# Exercise 8.12(e)(b)/(e)(d)(ii) (Scott 1981, PRG-19, Lecture VIII) -- a computable canonical
bisection for `V`, rerouted through the minimal presentation

## 8.12(e)(b)(i): `myFirstBit`, the least-set-bit search combinator

`V_no_minimal`'s classical proof (`Exercise812.lean`) picks its splitting bit `?_0` via a bare
existential (`levelSet_nonempty_iff.mp hne`). `LevelSetPrimrec.lean`'s existing `bExistsFn`
combinator only *decides* whether such a witness exists ( $\{0,1\}$ -valued); it never *produces* one
.
`myFirstBit m N` fills that gap: the smallest ` $? < N` with `m.testBit ? = true`, computed by
the
same bounded `Nat.rec`-fold idiom `bExistsFn`/`bForallFn` use, but threading the witnessing
index
itself through the recursion instead of a ` $\{0,1\}$ ` flag -- a sentinel value of `N` (never itself
a
valid index ` $< N` marks "no witness found among the indices scanned so far", exactly mirroring
`bExistsFn`'s own `0`-sentinel for "not yet found".
-/

namespace Scott1980.Neighborhood

open Domain.Recursive

/-! ### `myFirstBit`: definition -/

/-- **The least-set-bit search combinator.** `myFirstBit m N` is the smallest ` $? < N` with
`m.testBit ? = true`, or `N` itself (a sentinel, since a genuine witness is always ` $< N` if no
such ` $?` exists. Folds over `i = 0, 1, ..., N - 1` in increasing order (via `Nat.rec` on `N`,
mirroring `bExistsFn`'s recursion exactly): once a witness has been found (the running value is
`< i`), it is carried forward unchanged; otherwise (`ih = i`, nothing found yet) bit `i` itself
is
tested, becoming the new witness if set, or `i + 1` (the new sentinel) if not. -/
def myFirstBit (m N : Nat) : Nat :=
  Nat.rec (motive := fun _ => Nat) 0
    (fun i ih => selectFn (isZero (i - ih)) (selectFn (myTestBit m i) i (i + 1)) ih) N

/-! ## 8.12(e)(b)(ii): `myClearBit`, a computable "clear one bit" primitive

`V_no_minimal`'s classical proof needs `M ^^^ 2 ^ ?_0` (Mathlib's `Nat.xor`, not exposed as
`Nat.Primrec` -- the reason `myLor`/`myUpsample` etc. had to be hand-built already, per
`LevelSetPrimrec.lean`'s own header). Since `?_0` is always already known set in `M` at the
point
of use (`myFirstBit_testBit`, `(e)(b)(i)`), a plain truncated subtraction suffices as the
computable stand-in: clearing a *known-set* bit is the same as subtracting its power of two.
`myClearBit_eq_xor` bridges the two, so every downstream argument can keep using Mathlib's own
`Nat.testBit_xor`/`Nat.testBit_two_pow` unchanged, exactly as `V_no_minimal`'s original proof
does. -/

/-- **The "clear one bit" primitive.** `myClearBit m ? := m - 2 ^ ?` -- primitive recursive for
free (plain subtraction and a power of two), and, whenever bit `?` of `m` is genuinely set,
literally equal to `m ^^^ 2 ^ ?` (`myClearBit_eq_xor`). -/
def myClearBit (m ? : Nat) : Nat := m - 2 ^ ?

theorem primrec_myClearBit : Nat.Primrec (fun t => myClearBit t.unpair.1 t.unpair.2) := by

/-! ## 8.12(e)(d)(ii): the minimal presentation of `VX n`, at the code level

`canonIdx n`'s raw `(level, mask)` pair is not a presentation-independent invariant of the
set
`VX n` (`MinLevel.lean`'s header, `(e)(d)(i)`'s discovery) -- the same set can be `canonIdx`-
canonical at arbitrarily many different levels via repeated `myUpsample`. `MinLevel.lean`
supplies
the genuine invariant: `(minLevel, minMask)` applied to `canonIdx n`'s own pair. Every
downstream
definition in this file is now built from `splitVMinLevel`/`splitVMinMask` (below) rather than
`(canonIdx n).unpair.1`/`.unpair.2` directly, so that `splitVLeft`/`splitVRight`'s *outputs* --
in
fact, as it turns out, their raw *indices* (`splitVLeft_eq_of_congr`/`splitVRight_eq_of_congr`,
stronger than the `left_congr`/`right_congr` fields actually demand) -- depend only on `VX n`
as a
set, delivering `ComputableBisection.left_congr`/`right_congr` for `(e)(d)(iii)`. -/

/-- The presentation-independent canonical level of `VX n`. -/

/-! ## 8.12(e)(b)(iii): `splitVLeft`/`splitVRight` -- the actual computable split

Follows `V_no_minimal`'s construction (`Exercise812.lean`, Scott's remark after Definition 8.7)
verbatim, at the code level: take `(k, m) := (splitVMinLevel n, splitVMinMask n)` -- the *
  minimal*
  presentation of `VX n` (`(e)(d)(ii)`; before the reroute this was `canonIdx n`'s own, possibly
  non-minimal, pair) -- upsample `m` one level finer (`M := myUpsample k (k+1) m`), pick the
  splitting
  bit `?_0` as `M`'s least set bit (`myFirstBit`, `(e)(b)(i)` -- the classical proof instead
  draws `?_0`
  from a bare existential `levelSet_nonempty_iff.mp hne`, bounded by  $2^k$ ; here it is found
  directly on the *upsampled* mask `M`, bounded by  $2^{k+1}$ , which is fine since `upsample`
  duplicates every set bit of `m` into a matching pair at level `k+1`, so *any* set bit of `M`
  has a
  genuine "twin" -- `(e)(b)(iv)`'s job to make precise). `splitVLeft`/`splitVRight` then package
  `Y :=
  levelSet (k+1) (2?_0) / `Z := levelSet (k+1) (M?? 2?_0)` (`V_no_minimal`'s own `Y`/`Z`) as
  codes,
  using `myClearBit` (`(e)(b)(ii)`) as the computable stand-in for `???`. -/

/-- The upsampled mask `M := myUpsample k (k+1) m` for `(k, m) := (splitVMinLevel n,
  splitVMinMask
  n)` -- Scott's `M` from `V_no_minimal`, at the code level, fed the *minimal* presentation. -/
def splitVUpsampled (n : Nat) : Nat :=
  myUpsample (splitVMinLevel n) (splitVMinLevel n + 1) (splitVMinMask n)

/-! ## 8.12(e)(b)(iv): correctness -- `VX_splitVLeft`/`VX_splitVRight`, `splitV_disjoint`,
    `splitV_union`

Transcribes `V_no_minimal`'s `hInter`/`hUnion` computations (`Exercise812.lean` lines 242-261)
to
the `splitVLeft`/`splitVRight` code level, substituting `myFirstBit`'s spec for the classical
`hbit`/`?_0` and `myClearBit_eq_xor` for the raw `~~~~` occurrences. The one genuine addition
beyond
a verbatim transcription: since `splitVBit`'s `?_0` ranges over the *whole* `[0, 2^(k+1))` (
found on
the upsampled mask `M` directly, per `(e)(b)(iii)`'s docstring) rather than being handed a
priori
as `< 2^k` with a fixed twin `?_0 + 2^k`, `splitV_twin_testBit` below establishes the general
twin-bit fact (`M`'s bit `?_0 ^ 2^k` is set whenever bit `?_0` is) needed for `VX_splitVRight`
's
nonemptiness -- proved directly from `levelSet_myUpsample` (no fresh `testBit`-level `
myUpsample`
lemma needed), by reducing both `?_0` and its twin mod `2^k` and observing they agree there. -/

/-- `splitVUpsampled n`'s mask always has *some* set bit below `2^(k+1)` -- inherited from
`VX n` always being non-empty (`VX_nonempty`), transported to the *minimal* presentation via
`levelSet_splitVMin`, then one level up via `levelSet_myUpsample`. Feeds
`myFirstBit_lt`/`myFirstBit_testBit`. -/

/-! ## 8.12(e)(d)(ii): `splitVLeft_congr`/`splitVRight_congr`

The payoff of the reroute through `splitVMinLevel`/`splitVMinMask`: since `splitVMin_congr`
shows
two codes presenting the *same* `VX`-set route through the identical minimal `(level, mask)`
pair,
every downstream quantity built from it (`splitVUpsampled`, `splitVBit`, and hence `splitVLeft`
`/`
`splitVRight` themselves) is *literally* the same raw index, not merely presenting the same set
--
strictly stronger than the `ComputableBisection.left_congr`/`right_congr` fields actually
demand,
proved first as `splitVLeft_eq_of_congr`/`splitVRight_eq_of_congr` below and then downgraded.
-/

/-- **`splitVLeft`'s raw index is presentation-independent** (stronger than `left_congr` needs)
:
two codes presenting the same `VX`-set produce the *literally identical* `splitVLeft` index,
since
`splitVMin_congr` forces `splitVUpsampled`/`splitVBit` to agree exactly. -/

# Exercise 8.12(f), prerequisite -- `V` has a computable set-difference (`IsComputableDiff`)

`Exercise812d.lean`'s `IsComputableDiff` `(d)(3)(a)` has so far only been instantiated for `U`
(`Exercise812eD.lean`'s `U_isComputableDiff`/`Udiff`). This file supplies the missing `V`-side
instance, `V_isComputableDiff`, needed by `8.12(f)`'s `splitFromBisection`
  VComputablePresentation
... UComputableBisection` (`V` is the prober for `(f)`, symmetric to `U` being the prober for
`(e)`).

## Design

Mirrors `LevelSetPrimrec.lean`'s `VinterRaw`/`Vinter` exactly, substituting `Exercise812c.lean`
`s
`levelSet_diff` for `levelSet_myInter` as the driving mathematical fact. `levelSet_diff`'s
formula
combines two upsampled masks via the bitwise "and-not" identity `a ~~~ (a &&& b)`
(`testBit_xor_and_self`) instead of plain `&&&` -- so the one new piece of `Nat.Primrec`
infrastructure needed is a computable version of that combinator. Rather than re-deriving the
"and-not" identity arithmetically, we build a fresh choice-free primitive-recursive bitwise XOR
(`myXor`), mirroring `myLand`/`myLor` bit-for-bit (`lowXor`/`xorStep`, `Nat.testBit_xor` in
place of
`Nat.testBit_and`/`Nat.testBit_lor`), and simply compose it with the already-`Pass` `myLand`:
`myAndNot a b := myXor a (myLand a b)` realizes `a ~~~ (a &&& b)` for free from
`myXor_eq_xor`/`myLand_eq_land`, no new arithmetic identity needed.
-/

# Exercise 8.12(f), prerequisite -- a *presentation-independent* canonical bisection of `U`

`SplitU.lean`'s `splitULeft`/`splitURight` (built for Theorem 8.8(b)) split `X_n` at the
midpoint of
`canonCode n`'s **first presenting pair** -- but `canonCode` only clips/filters, it never *
merges*
overlapping or adjacent intervals, so two different (both already-canonical, in the sense of

```

`canonList\_fixed`) presenting lists of the *same* `U`-neighbourhood can have different first pairs (e.g. $[(0,1)]$ vs. $[(0, 1/2), (1/2, 1)]$ both present `U.master`, but their first pairs' midpoints are $1/2$ and $1/4$). So `splitULeft`/`splitURight` do **not** satisfy `ComputableBisection`'s `left\_congr`/`right\_congr` -- this is a genuine gap in reusing `SplitU.lean` "as is" for `8.12(f)`, mirroring the gap `MinLevel.lean` fixed for `V`'s side of `8.12(e)(d)`.

The fix: split at the midpoint of `(min, max)` instead of the first pair

Rather than building full interval-merging machinery (as `MinLevel.lean` effectively had to for `V`'s levels), a much lighter invariant suffices here: for a finite union of half-open rational intervals $X = \bigcup p_{i.1} p_{i.2}$,

* $\min X = \min_i p_{i.1}$ (attained -- every `Ico` is left-closed, and every point of the union is $\geq$ some $p_{i.1}$), and
 * $\sup X = \max_i p_{i.2}$ (not necessarily attained, but this is *still* a fact purely about the set X , not about which particular representing list computes it -- $\sup$ of a finite union is the $\max$ of the individual $\sup$'s, and each $\text{Ico } p_{i.1} p_{i.2}$ has $\sup = p_{i.2}$).

Both quantities are therefore genuinely **intrinsic** to the set X , not to the specific presenting list -- so splitting at their midpoint is automatically presentation-independent, with no

need to ever canonicalize/merge/sort the interval list itself. `listMinFst`/`listMaxSnd` below compute exactly these two quantities as primitive-recursive folds over `canonCode n`'s list, reusing

`SplitU.lean`'s `clipLtListCode`/`clipGeListCode` unchanged for the actual clipping.

# Exercise 8.12(f) (Scott 1981, PRG-19, Lecture VIII) -- `V` satisfies the extension property
relative to `U`

The mirror image of `Exercise812eD.lean`'s `8.12(e)`: there `U` was the prober against `V`'s
canonical bisection (`SplitV.lean`'s `B812e`); here `V` is the prober against `U`'s canonical
bisection. Given `(e)(c)`'s generic `splitFromBisection`/`isComputableSplit_ofBisection`
(`Exercise812e.lean`), this is a one-line instantiation, fed:

* `VComputablePresentation` (`VComputablePresentation.lean`) as the prober `P`;

```

```

* `V_isComputableDiff` (`VDiff.lean`) as `P`'s `IsComputableDiff` witness -- the missing
prerequisite this development had to supply first (`U`'s side, `Udiff`/`U_isComputableDiff`,
was
already built for `(e)(d)`, but `V`'s side had never been instantiated);
* `UBisection2` (`UBisection2.lean`) as the target `U`'s `ComputableBisection` -- **not**
`SplitU.lean`'s `splitULeft`/`splitURight`, which split at the midpoint of `canonCode n`'s *
first*
presenting pair and so fail `ComputableBisection`'s `left_congr`/`right_congr` (two different
canonical presenting lists of the same `U`-neighbourhood can have different first pairs). `
UBisection2`
instead splits at the midpoint of the presented set's own intrinsic `(min, max)` -- genuine
invariants of the set, not of its presentation -- restoring well-definedness at no cost to
any of
`(e)(c)`'s other requirements.
* `V`'s already-`Pass` `IsPositive`/`NoMinimal`/`DiffClosed` facts (`Exercise812c.lean`),
needed only
for `isComputableSplit_ofBisection`'s correctness obligations (`(e)(c)`'s own congruence
lemmas),
exactly mirroring `(e)(d)`'s use of `U`'s analogous facts.

# Exercise 8.12(g)(1)(a) -- the `U`-side small assembly prerequisites

Two small facts `effectiveIso812d` (`Exercise812d.lean`) needs beyond `(c)`/`(d)`/`(e)`/`(f)`'s
own
headline lemmas, for the `U` side: `U.master.Nonempty` (`hD_Omne`) and `UX 0 = U.master` (`hX0`
`).

Both are short and mechanical, reusing existing machinery with no new mathematical content:
`U.master.Nonempty` is immediate from `U.master = Set.Ico 0 1`; `UX_zero` unfolds `UX_eq` at `n
= 0`
(`decodeQPairList 0 = []` via `decodeList_zero`), so `canonList` hits its own empty-input
fallback
branch (`canonList_eq_of_filter_eq_nil`), landing on the same `[(0,1)] |-> U.master`
computation
`U_mem_presentedIntervals_canonList` already performs inline.
-/

namespace Scott1980.Neighborhood

# Exercise 8.12(g)(1)(b) -- the `V`-side small assembly prerequisites

```

Two small facts ``effectiveIso812d`` (``Exercise812d.lean``) needs beyond ``(c)`/`/(d)`/`/(e)`/`/(f)`'s` own headline lemmas, for the ``V`` side: ``V.master.Nonempty`` (``hD_1mne``) and ``VX 0 = V.master`` (``hY0``).

Mirrors ``Exercise812g1a.lean``'s ``U``-side facts exactly, but along ``V``'s bitmask representation: ``V.master.Nonempty`` is immediate from ``V.master = Set.univ``; ``VX_zero`` unfolds ``canonIdx 0`` -- since ``Nat.unpair 0 = (0, 0)`` and ``levelSet 0 0 = {}`` (no bits set in ``0``), ``canonIdx`` hits its own empty-input fallback branch (``canonIdx_eq_master_of_empty``), landing on ``VmasterIdx``, whose ``VX``-image is already known to be ``V.master`` (``VX_VmasterIdx``).

```

# Exercise 8.12(g)(2) -- `IsComputableUnion` for `U` and `V`

`Exercise812d.lean`'s `(d)(4)(a)` defines `IsComputableUnion` (mirroring `IsComputableDiff`'s
shape
for `U` instead of `V`) but never instantiates it for either concrete system. Both instances
turn
out unconditional: unlike `IsComputableDiff`'s `diffIdx_spec`, whose hypothesis is
genuinely
```

needed (a difference can be empty), a union of two genuine, non-empty neighbourhoods is **always*
 *
 again a genuine neighbourhood for both `U` and `V` -- so `unionIdx\_spec`'s hypothesis, while
 still
 accepted (to match the structure's shape), is never actually used, and `union\_computable`
 reduces
 to the trivial always-`1` decider.

```
* **`U`-side** (`Union`): mirrors `Exercise812eD.lean`'s `Udiff`, substituting the raw list
  -`++`
  primitive `appendListCode` (`Recursive.lean`) for `diffCode` -- concatenation trivially
  witnesses
  `presentedIntervals`'s own closure under `U` (`presentedIntervals_append`, `Definition87.
  lean`).
* **`V`-side** (`Vunion`): mirrors `LevelSetPrimrec.lean`'s `VinterRaw`/`Vinter`, substituting
  the
  bitwise-OR primitive `myLor` for `myLand` (`levelSet_myUnion`, the computable version of
  `Exercise812.lean`'s inlined union identity already used in `V_union_mem`).
-/

# Exercise 8.12(g)(4) (Scott 1981, PRG-19, Lecture VIII) -- final assembly: `U ~ V`

The exercise's ultimate target: `U` and `V` are effectively isomorphic. A one-line
  instantiation of
`Exercise812d.lean`'s generic `effectiveIso812d` (`(d)(6)`'s `EffectiveIso` assembly), fed
  every
concrete `U`/`V` fact this development has built:

* `(e)(d)`/`(f)`: `U_isComputableDiff`/`V_isComputableDiff`, `splitX812e`/`
  isComputableSplit_812e`,
  `splitX812f`/`isComputableSplit_812f`;
* `(g)(3)`: `hxSplit812e : SplitSpec' V splitX812e`, `hySplit812f : SplitSpec' U splitX812f`

```

```

(`Exercise812eD.lean`/`Exercise812f.lean`, completed above);
* `(c)`: `U_isPositive`/`U_diffClosed`/`U_noMinimal`, `V_isPositive`/`V_diffClosed`/`
  V_noMinimal`;
* `(g)(1)`: `U_master_nonempty`/`UX_zero`, `V_master_nonempty`/`VX_zero`;
* `(g)(2)`: `U_isComputableUnion`, `V_isComputableUnion`.

No new proof content -- every subgoal `effectiveIso812d` demands was already discharged by one
of
the above. -/

# Exercise 8.13(a) (Scott 1981, PRG-19, Lecture VIII) -- `V` *is* the free Boolean algebra on
`?_0`
generators

Exercise 8.13's "(for logicians)" half asks to show `U` is isomorphic to the domain of all
proper
filters of the free Boolean algebra on `?_0` generators. The key finding (see `arxiv.md`'s
`8.13`
scoping row) is that `Exercise812.lean`'s `V` -- `levelSet k m = {n | m.testBit (n % 2^k)}`,
already
known `~ = ? U` (`Exercise812g4.lean`) -- *already is* this algebra, concretely realized via
the bits
of `n : Nat`. This file makes that identification precise and complete:

* `generator i := {n | n.testBit i}`, the `?_0` generators (independent propositional variables
).
* `GeneratedBy generator` -- the Boolean subalgebra of `Set Nat` they generate.
* `V_mem_iff_generatedBy` -- **`V.mem X <-> GeneratedBy generator X /\ X.Nonempty`**: `V`'s

```

```

neighbourhoods are exactly the (non-empty) elements of this algebra. Since `V.Element`'s
defining filter conditions (`Basic.lean`'s `Element` -- upward closed, finite-meet-closed,
contains the top, and (via `V.mem` excluding `{}`) never contains the bottom) are precisely "
proper
filter of `{X | GeneratedBy generator X}`", this makes `V.Element` by definition the domain
of
proper filters of the algebra generated by `generator`.
* `generators_independent` -- the `generator i` are independent (every finite Boolean
combination is
non-empty), the standard combinatorial property characterizing "generates a free Boolean
algebra" (a citation, not a re-derivation, of the universal-algebra fact that a countable
Boolean
algebra with countably many independent generators is the free Boolean algebra on `?_0`
generators
-- `= the Lindenbaum algebra of propositional calculus` per `8.13`'s own gloss, see `8.13(b)`
for
the optional literal formula-syntax bridge).
* `exercise813a` -- the headline:  $U \cong V$ , hence effectively `U` is isomorphic to the
domain of
proper filters of the free Boolean algebra on `?_0` generators, via `effectiveIso812_UV` (
already
`Pass`, `Exercise812g4.lean`). No new back-and-forth argument is needed at all.

# Exercise 8.13(b) (Scott 1981, PRG-19, Lecture VIII) -- the Lindenbaum algebra bridge

`8.13`'s parenthetical gloss -- "the free Boolean algebra on `?_0`-generators (= **the
Lindenbaum
algebra of propositional calculus**)" -- equates *the algebra itself* with a syntactic quotient
of
propositional formulas. `Exercise813a.lean` already built (and used, to answer `8.13`'s actual
"prove that `U` is isomorphic to..." content) a concrete realization of that algebra,
`{X : Set Nat | GeneratedBy generator X}`. This file makes the parenthetical literal: a `
Formula`
syntax, its semantics `evalV`, the Lindenbaum quotient `Formula ? SemanticEquiv`, and a
bijection
(`Lindenbaum.toSet`) from that quotient onto `Exercise813a.lean`'s concrete algebra -- plus
`entails_iff_evalSet_subset`, showing the bijection also matches semantic entailment with `
subsetq`, i.e.
it is an order (not just a set) correspondence.

Per the scoping discussion, this is *optional/expository*: `8.13`'s actual "prove that..."
content
was already fully answered by `Exercise813a.lean` alone. Nothing here changes that; it only
makes
the naming in the parenthetical literal instead of asserted.

## What's proved

* `Formula`, `evalV` -- a minimal propositional-logic syntax (`?_0` variables) and its standard
truth-valuation semantics.
* `evalSet` -- the *same* recursion, interpreted in `Set Nat` via `Exercise813a.lean`'s `
generator`.
* `mem_evalSet_iff` -- the bridge: `n in evalSet phi <=> evalV (fun i => n.testBit i) phi =
true`.
* `generatedBy_iff_exists_evalSet` -- `evalSet`'s range is exactly `GeneratedBy generator`.
* `SemanticEquiv`/the `Formula` `Setoid` -- Scott's own equivalence relation for the Lindenbaum
algebra (`phi ~ psi` iff they agree under every valuation).
* `semanticEquiv_iff_evalSet_eq` -- the one substantive lemma: semantic equivalence (
quantifying
over *all* `v : Nat -> Bool`) agrees with `evalSet`-equality (which only ever "tests" the
countably
many valuations arising from a natural number's own bits), because a single formula only
mentions finitely many variables (`exists_bitsOf_agree` supplies a matching bit-derived
valuation for any finite variable set).
* `Lindenbaum := Quotient (formulaSetoid)`, `Lindenbaum.toSet`, `Lindenbaum.toSet_injective`,
```

```

`Lindenbaum.range_toSet` -- **the headline**: `Lindenbaum` (Scott's Lindenbaum algebra of
propositional calculus) bijects, via `toSet`, onto `{X | GeneratedBy generator X}`
(`Exercise813a.lean`'s free Boolean algebra on `?_0` generators).
* `entails_iff_evalSet_subset` -- the bijection also matches semantic entailment with `
  subseteq`, so it
  respects order (hence the Boolean-algebra structure), not just underlying sets.

# Exercise 8.13(c) (Scott 1981, PRG-19, Lecture VIII) -- connecting to Cantor space

> (For topologists.) Connect this representation of `2^Nat` with the collection of non-empty open
> subsets of the product space `2^Nat` (= Cantor space).

Per the scoping in `arxiv.md`, the literal "proper filters `?o` non-empty opens" reading is
**false** (every filter contains `master`, so the naive map is constant); the mathematically

```

```

correct route lands on "opens" via the *dual* notion (**ideals**), decomposed into four
  subgoals
`8.13(c1)`-`(c4)`. This file carries `8.13(c1)`-`(c3)`.

## `8.13(c1)`: Cantor space's clopen algebra is `GeneratedBy genPoint`

`genPoint i := {x : Nat -> Bool | x i = true}` is the literal transcription, on carrier `Nat
-> Bool`,
of `8.13(a)`'s `generator i` (on carrier `Nat`). The headline, `
  isClopen_iff_generatedBy_genPoint`,
identifies Cantor space's clopen algebra with `GeneratedBy genPoint` exactly:

* `?` (`generatedBy_genPoint_isClopen`) is easy structural induction: each `genPoint i` is
  clopen
  (preimage of a clopen singleton in discrete `Bool` under the continuous projection), and
  clopens
  are closed under the Boolean operations `GeneratedBy` builds with.
* `?` is the substantive direction, via compactness: every open `Y` is covered by `box`es
  (`box I f := {x | forall i in I, x i = f i}`, one finite-support box per point of `Y`,
  from
  `isOpen_pi_iff` -- Bool's discreteness lets us shrink to a singleton box at each coordinate)
  each
  contained in `Y`; each `box` is itself `GeneratedBy genPoint` (`generatedBy_genPoint_box`, by
  `Finset.induction_on`); `Y` clopen (hence compact, as Cantor space is a `CompactSpace`)
  extracts
  a **finite** subcover, so `Y` is a finite union of `box`es, hence `GeneratedBy genPoint` by
  `generatedBy_genPoint_biUnion`.

`isOpen_iff_iUnion_genPoint` records the immediate corollary that opens (not just clopens) are
exactly unions of `GeneratedBy genPoint` sets -- the "topological basis" fact `8.13(c)`'s
  scoping
row anticipated, now free from the clopen identification.

## `8.13(c2)`: `generator`/`genPoint` realize the same free Boolean algebra

`8.13(b)`'s `Formula`/`evalV` already has one evaluation, `evalSet : Formula -> Set Nat`
(`var i |> generator i`). A *second* evaluation, `evalSet' : Formula -> Set (Nat -> Bool)`
(`var i |> genPoint i`), is even simpler than the first: since Cantor space's own points
`x : Nat -> Bool` already *are* valuations, `mem_evalSet'_iff` needs no bit-encoding step (
  unlike
`8.13(b)`'s `mem_evalSet_iff`, which had to translate `n : Nat` into a valuation via its bits)
--
and consequently `semanticEquiv_iff_evalSet'_eq` needs no finitary agreement argument either.

`Corresponds X Y := exists phi, evalSet phi = X /\ evalSet' phi = Y` witnesses, via a common
`Formula`, that
`generator`'s algebra `{X | GeneratedBy generator X}` and `genPoint`'s algebra
`{Y | GeneratedBy genPoint Y}` are "the same" abstract Boolean algebra: `Corresponds` relates
them
functionally in both directions (`exists_corresponds_of_generatedBy_generator/genPoint`,
`Corresponds.unique_left/right`) and respects `subseq` (`Corresponds.subset_iff`) -- i.e.
it is exactly
an order-isomorphism between the two concrete algebras, without needing any (nonexistent)
bijection
of the wildly different underlying carriers `Nat`/`Nat -> Bool`.
-/

## `8.13(c3)`: ideal/filter complementation

A general, `g`-generic toolkit (not specific to Cantor space): for a Boolean subalgebra of sets
`GeneratedBy g` closed under complement, `Y |-> Y?` turns a *downward*-closed, finite-join-
closed,
`univ`-excluding family (an **ideal**) into an *upward*-closed, finite-meet-closed, `{}`-
excluding,
`univ`-containing family -- i.e. exactly the four fields `8.13(a)`'s `V.Element`
(`Basic.lean`'s `NeighborhoodSystem.Element`) bundles as a "proper filter." `dualFilter` is
stated
as a plain `Set (Set a) -> Set (Set a)` operation (not a bundled structure) with each of the
four
properties as its own small lemma, so `8.13(c4)` can assemble a genuine `V.Element` term
directly

```

```

from them.

## `8.13(c4)`: assembly

For an open `0 subseq 2^Nat` with `0 != Set.univ`, `idealOf 0` ("the clopens inside `0`")
is a proper
ideal of `GeneratedBy genPoint`, so (`8.13(c3)`) `dualFilter (idealOf 0)` is a proper filter of
`GeneratedBy genPoint`; transporting through `Corresponds` (`8.13(c2)`) gives a proper filter
of
`GeneratedBy generator`, i.e. (`8.13(a)`) a genuine element of `V` (hence, via `exercise813a`,
of
`U`) -- `elementOfOpen`.

```

****On Scott's "non-empty":**** taken at face value this is the *wrong* exclusion for this specific construction. Emptiness of ``0`` never breaks properness here -- ``idealOf {} = {}`` dualizes to the filter ``{Set.univ}``, the perfectly legitimate (if degenerate) ****bottom**** element of ``U``. What actually breaks properness is ``0 = Set.univ``: then ``idealOf 0`` contains ``Set.univ`` itself (violating "excludes ``univ``"), and dualizing produces a "filter" containing ``{}`` -- exactly what ``V.Element``'s ``sub`` field (via ``V_mem_iff_generatedBy``, which excludes ``{}``) forbids. So the precise hypothesis this construction needs is ``0 != Set.univ`` ("proper"), not ``0.Nonempty`` -- Scott's remark is informal here, consistent with the parenthetical's own looser phrasing (``arxiv.md``'s scoping already flagged the parallel "opens vs. closed" imprecision).

```

/-- The clopens contained in `0`: a proper ideal of `GeneratedBy genPoint` whenever `0 !=
    univ`. -/

# Exercise 8.14 (Scott 1981, PRG-19) -- closure operators and the fixed-point domain

**Exercise 8.14.** A retraction  $a : D \rightarrow D$  is called a closure operator iff  $\text{I}_D \sqsubseteq_{\text{sub}} a$ . On a
domain like  $\text{PN}$ , give some examples of closure operators. Prove in general for any closure
 $a : D \rightarrow D$  that the fixed-point set of  $a$  is always a finitary domain. What are the finite
elements of the fixed-point set?

## Scope

The exercise's imperative ("prove in general... that the fixed-point set is always a finitary
domain", plus "what are the finite elements") is genuinely new mathematical infrastructure (no
general "algebraic-domain-from-a-poset-of-compacts" construction existed anywhere in the
project
before this file) and is the substantive content proved here in full. The "give some examples
...
close up a set of integers under addition... is this continuous?" prompt is expository (Scott
already has  $\text{PN}$  available, Example78.lean); it is not needed to answer the exercise's actual
imperative and is left as an optional, non-blocking follow-up (see HANDOFF.md).

## The mathematical content

A closure operator is a retraction  $a : E \rightarrow E$  with  $\text{I}_E \sqsubseteq_{\text{sub}} a$  (IsClosureOperator
), i.e.  $a$ 
is inflationary:  $y \sqsubseteq_{\text{sub}} a(y)$  for every  $y$  in  $|E|$  (le_toElementMap_of_isClosureOperator). Since
 $a$  is also idempotent (toElementMap_idem) and monotone, its fixed-point set  $\text{Fix}(a)$  (FixSet a,
already defined in Theorem85.lean) is:

* closed under directed unions (toElementMap_iSupDirected_fixed, already proved
generically in
Theorem85.lean for any retraction -- Scott's first hint, "closed under ... directed
unions",
needs no new work here);
* has a least element  $a(\text{False})$  (botFix, botFix_le:  $a(\text{False}) \sqsubseteq_{\text{sub}} y$  for every  $y$ 
in  $\text{Fix}(a)$ , since
 $\text{False} \sqsubseteq_{\text{sub}} y$  and  $a$  is monotone and  $y$  is already fixed);
* closed under existing bounded joins, computed as  $a(\sqsupset \{y_1, y_2\})$  for the ordinary
 $E$ -supremum

```

```

`sqsup` (Exercise 1.27's `sSup`) of a bounded pair -- this is Scott's second hint, "closed
under ...
intersections", read correctly: the fixed-point set is a sub-*join*-semilattice of  $|E|$  (not
literally closed under *arbitrary* intersections of  $|E|$ , which would need nothing about  $a$ 
at
all -- see `Basic.lean`'s `Exercise118.sInf` -- but under the *joins* that make it algebraic)
.

The genuinely new piece is the compact-element theory:  $a(X)$ , for any  $E$ -neighbourhood  $X$ 
,
is compact w.r.t. directed unions within  $\text{Fix}(a)$  (isCompactFix_toElementMap_principal)
even
though it typically is not itself principal in  $E$  (the standard example: closing  $\{n\}$  under
addition in  $\mathbb{N}$  needs infinitely many tokens to describe as a subset of  $\mathbb{N}$ , but is still a
"finite" piece of information about the closure). Finite *joins* of such compacts (when bounded
)
are again compact (isCompactFix_sup), which is exactly what is needed to reconstruct a
genuine
`NeighborhoodSystem` (domainOfClosure) whose tokens are the compact fixed points
(CompactFix) and whose neighbourhoods are their principal up-sets (upFix); its Element
type is shown order-isomorphic to  $\text{Fix}(a)$  (fixSetOrderIso), giving IsFinitary a
(isFinitary_of_isClosureOperator) -- Scott's main request.

Finally, the finite elements are answered exactly:  $y$  in  $\text{Fix}(a)$  is compact iff  $y = a(X)$ 
for
a single  $E$ -neighbourhood  $X$  (isCompactFix_iff) -- the apparent need for *finite joins*
above is
only a bookkeeping device to build the ambient NeighborhoodSystem; every individual compact
element, once shown compact, collapses back to a single generator by a sandwich argument (y
sqsub
a(X) sqsub y for  $X$  witnessing algebraicity's directed decomposition of  $y$ , using
compactness to
extract one  $X$  from the direct limit). This matches Scott's own "close up *a set* under
addition"
phrasing: the finite elements of the fixed-point domain are precisely the closures of the (
already
finite) neighbourhoods of the ambient domain.

Everything is choice-free (#print axioms subseteq {propext, Quot.sound}), inheriting
the same
baseline as Theorem85.lean`/`Exercise127.lean`.

/-! ### What are the finite elements of the fixed-point set? -/

/-- **Exercise 8.14, the final question, answered exactly.** `y` in  $\text{Fix}(a)$  is compact (i.e.
  is a
  *finite element* of the fixed-point domain) iff `y = a(X)` for a single `E`-neighbourhood `
  X`.
  The forward direction is a sandwich argument: `y` is the directed union of the compacts `a(X)`
  (`X` in `y`, `toElementMap_eq_iSupDirected_genFamily`), so compactness pulls out a single
  witness `X`
  with `y` sqsub `a(X)`; the reverse inequality `a(X)` sqsub `y` is automatic since `X` in `y`.
  -/

# Exercise 8.15 (Scott 1981, PRG-19) -- `{X ? X ? D}` is effectively presented if `D` is

Following Dana Scott, *Lectures on a Mathematical Theory of Computation*, PRG-19, Lecture VIII.

> **Exercise 8.15.** Give a *direct* proof that the domain `{X ? X ? D}` is effectively
  presented

```

```
> if `D` is. (Hint: the finite elements of the domain correspond exactly to the finite systems
> `X ? D`.) In the case of `D = ?`, show that the computable elements of the domain correspond
> exactly to the effectively presented domains (up to effective isomorphism).
```

```
Scott's `{D' ? D' ? D}` (ordered by the subsystem relation `?`, Definition 6.10) is already
known to
*be* a domain: Proposition 6.11 (`Proposition611.subsystemReprIso`) exhibits it as order-
isomorphic to
`|reprSystem (subFam D) ...|`, via the **abstract, `Classical.choice`-laden** representation
theorem of
Exercise 2.22. Scott explicitly asks here for a *direct* proof of effective presentability, and
the
hint ("finite elements <-> finite systems `X ? D`") points at a concrete, `Nat`-indexed
reconstruction
instead -- reusing `Theorem75.lean`'s `interFrom`/`idxchain`/`bitSelect`/`decodeList` toolkit (
built
there for exactly this kind of "finite consistent sub-selection" bookkeeping).
```

```
## Plan (recorded in `HANDOFF.md` and `arxiv.md`, worked in sequence)
```

```
Fix `D` : NeighborhoodSystem a` and a `ComputablePresentation P` of `D`.
```

1. **`Fin(js)`**, the finitely generated subsystem** (this file's `finGen`/`finGenSys`): for a finite index list `js : List Nat`, the set of *consistent sub-meets* `Fin(js) := {Y ? exists sub sqsub js, D.mem Y /\ Y = interFrom P D.master sub}`. This is itself a subsystem `finGenSys(js) ? D`, and **`Fin\_le\_iff\_forall\_mem`**: `Fin(js) subteq D'.mem <-> forall i in js, D'.mem (P.X i)` for any `D' ? D` -- the single workhorse lemma for everything downstream (proved by induction on `js`, using `interFrom\_mem\_of\_witness` from `Theorem75.lean` to handle "an intermediate partial meet along a consistent chain is itself consistent").
2. **The reconstructed system `SubD`** (token type `List Nat`): neighbourhoods are the anti-monotone principal up-sets `nbhd(js) := {js' ? Fin(js) subteq Fin(js')}`.
3. **The order isomorphism `SubD.Element ?o {D' ? D' ? D}`** -- fully choice-free, unlike Exercise 2.22.
4. **`ComputablePresentation SubD`** -- Scott's two relations reduce to *bounded* quantifiers over `bitSelect`-selected sub-lists, decided via `consChain\_iff`/`idxchain\_spec`/`P.eq\_computable`.
5. **Main theorem**: `D.IsEffectivelyGiven -> {D' ? D' ? D}` is (isomorphic to) an effectively given domain.
6. (Second half, `D = ?`): deferred pending 1-5.

/#! ### The remaining gap: `inter`/`cons_computable` need a term-algebra encoding (resolved
  below)

`Q'X r` (above) is a fully choice-free, primitive-recursive **enumeration of `D'x`'s
  neighbourhoods,
  onto** (`Q'x_mem_X`, `Q'x_surj`) -- the enumeration half of a `ComputablePresentation D'x`.
  Completing
  the *rest* of the structure (`inter`, `inter_spec`, `cons_computable`; `interEq_computable`
  alone is
  fine, a pure reindexing of `U_interEq_computable` along the primitive-recursive `Q'Xcode r`)
  hits a
  **newly-identified obstacle, sharper than the one logged previously**:

The natural candidate `Q'inter r n m := encodeList (decodeList n ++ decodeList m)` -- extending
  `n`'s

```

list by ``m``'s and re-folding -- does *not* satisfy ``inter_spec``. The reason is that ``Uinter``'s dichotomy fallback is *not* "conservative": once a fold step falls back to ``U.master`` (discarding the true partial intersection), *continuing* the fold from ``U.master`` can "recover" and compute a smaller, unrelated value, rather than staying stuck at ``U.master``. Concretely: ``Q'X r (Q'inter r n m)``'s value depends on the entries of ``n``'s and ``m``'s lists *combined sequentially from scratch*, while ``Q'X r n`` and ``Q'X r m`` are each computed *independently* from ``U``'s master. If (say) ``Q'X r m``'s own fold happened to fall back internally (its true intersection was empty) while the *globally* combined fold does not, ``Q'X r n I Q'X r m`` (inflated by the fallback) and ``Q'X r (Q'inter r n m)`` (computed honestly) can be genuinely different sets -- even though both individually satisfy ``mem_X``. The alternative fix -- ``Q'inter r n m := Uinter (Q'Xcode r n) (Q'Xcode r m)`` (apply ``Uinter`` *once more* on top of the already-computed indices, correct by the existing, unconditional ``Uinter_spec``, no compounding at all) -- repairs ``inter`/`inter_spec`` cleanly, but then breaks ``cons_computable``: its witness ``exists k, Q'X r k subseq Q'X r n I Q'X r m`` needs ``k`` to be *of the form* ``Q'Xcode r`` applied to some ``n``, `m`-derived list-code`, and there is no way to name that code without already tracking, as part of ``Q'X``'s own index type, a closed-under-``Uinter``-combination term structure (i.e. re-indexing ``Q'X`` by a small term language ``{base list, combine n_1 n_2}`` via course-of-values recursion, mirroring ``Recursive.lean``'s ``tabCode`` pattern for a *different* recursively-defined code). Building that term algebra is genuinely comparable in size to Subgoal 4 itself (as flagged previously), and is *left as documented future work* -- this is a more precise diagnosis of the difficulty than the "extracting a witness from a ``Prop``" issue logged earlier (that issue is avoided entirely by ``Q'X`/`Q'Xcode`` being directly-defined functions throughout; the *actual* remaining obstacle is this purely arithmetic "safe composition of finitely many ``Uinter`` calls" question). See ``HANDOFF.md``'s 2026-07-06 checkpoint.

Resolution (below): a binary term algebra fixes ``inter`/`cons_computable`` cleanly. The fix is to stop indexing ``D'x``'s neighbourhoods by *lists* folded left-to-right through ``Uinter`` (not compositional under concatenation, as diagnosed above), and instead index them by a *binary term algebra* -- codes for ``leaf j |-> r j`` and ``node t1 t2 |-> Uinter (val t1) (val t2)`` -- so that combining two already-built codes is *literally* the ``node`` constructor, staying inside the index type by construction (no search needed to name the combined index, unlike the list-code domain). -/

/-! ### The term algebra codes: ``leaf j``, ``node t1 t2``, ``master``

Evaluating a code needs *course-of-values recursion* (a ``node``'s two children are only known ``<=`` the parent via ``Nat.unpair``, not decreasing by a fixed amount), for which we reuse the *already-built*, generic ``fuelTable`/`fuelTable_eq_of_recursion`/`primrec_fuelTable`` machinery from ``Recursive.lean`` (built there for ``decodeFuelOkChar`/`autStateCardFuelChar``) rather than re-deriving course-of-values primitive recursiveness from scratch. -/

/-! ### 6g -- scope note: the fully general "arbitrary presentation" converse

  `subsystemU_effectivelyGiven_of_isComputableElement` reads Scott's "computable elements
  correspond
  to effectively presented domains (up to effective isomorphism)" via the *specific* presentation
  `Q'xPresentation` built **relative to** `UComputablePresentation`'s own enumeration** -- the
  natural,
  provable reading identified in the Subgoal 6 planning note above (a disjoint-interval example
  shows
  `x.mem (nbhdGen UP js)` does **not** imply `?.mem (interFrom UP ?.master js)` in general, so an
  *arbitrary*, unrelated abstract presentation `Q : ComputablePresentation D'x` cannot be
  compared to
  `UP` without extra structure).

  The fully general converse Scott's parenthetical "(up to effective isomorphism)" is gesturing
  at --

```

```

that *every* computable presentation of `D'x`, however constructed, is effectively isomorphic
to
`Q'xPresentation` -- is a genuine "uniqueness of computable numberings" fact (a Rogers-style
theorem:
two numberings of the same recursively enumerable structure that both make its structural
relations
decidable must be effectively translatable into each other). This is strictly deeper than
anything
Definition 7.1's axioms hand us directly, is not needed for the "correspond to" reading already
established by `subsystemU_effectivelyGiven_of_isComputableElement`, and is deliberately left
out
of scope** here. -/

# Exercise 8.16 (Scott 1981, PRG-19)

> **Exercise 8.16.** For finitary projections  $a : E \rightarrow E$ , write  $D_a = \{X \text{ in } E \mid X \sqsubseteq aX\}$  (cf. 8.5).
> Show that for any two such projections  $a, b : E \rightarrow E$  we have  $a \sqsubseteq b$  iff  $D_a \subseteq D_b$ .
  (This fills
> in the gap at the end of the proof of 8.6.) Also finish off the proof of 8.8 by showing that
  if
>  $E$  is effectively given and  $a : E \rightarrow E$  is computable, then  $D_a$  is effectively given.

## What is formalized here

Both halves turn out to already be (nearly) proved by existing machinery, so this file is a
thin
assembly layer:

* **Part 1** (isFinitaryProjection_le_iff_fixedNbhd_subsystem):  $D_a$  is exactly Theorem 8.5's
  fixedNbhd a, and  $a \leq b \iff \text{fixedNbhd } a \subseteq \text{fixedNbhd } b$  for finitary  $a, b$  is exactly
  Theorem
  8.6(a)'s order-isomorphism finitaryProjectionSubsystemEquiv ({f \mid f \sqsubseteq f} \cong \{D \mid D \subseteq E\}),
  where  $\leq$  on the right is literally ?, (Proposition611.lean), restricted from sub-fixed
  points to finitary projections via sub_eq_self_iff_isFinitaryProjection. We avoid depending
  on

```

```

the exact implicit-argument names of the generated `OrderIso.map_rel_iff` and instead
  assemble
both directions directly from `OrderIso.monotone`/`OrderIso.symm.monotone` plus
`OrderIso.symm_apply_apply`, which is robust to Mathlib's internal naming.
* **Part 2** (`exercise_8_16`'s second conjunct): already proved in full generality as
`Theorem88m.lean`'s `fixedNbhd_isEffectivelyGiven` -- "`a` computable relative to a
`ComputablePresentation P` of `E`" (`IsComputableMap P P a`) already packages "`E`
effectively
given (via `P`) and `a` computable (relative to `P`)"; no new proof is needed, only restating
it
under this exercise's name.

Everything here is **choice-free** (`subseq {propext, Quot.sound}`): Part 1 is built purely
  from order
theory on `finitaryProjectionSubsystemEquiv` (itself choice-free, Theorem 8.6(a)), and Part 2
  is a
direct citation of the already-audited choice-free `fixedNbhd_isEffectivelyGiven`.

# Exercise 8.17 (Scott 1981, PRG-19)

> **Exercise 8.17.** Find explicitly (if possible) the projection pairs for  $\text{`?+?`}$ ,  $\text{`? x ?`}$ , and
>  $\text{`? -> ?`}$  needed for 8.9. Are any of these domains isomorphic with  $\text{`??`}$  (The author does not
  know a
> really good construction for  $\text{`? -> ?`}$ .) Find a universal domain  $\text{`V`}$   $\text{!= ?`}$ .

## What is formalized here

**Part 1** (projection pairs for 8.9) is already fully answered by `Definition89.lean`: `iPlus/
jPlus`,
`iTimes/jTimes`, `iArrow/jArrow` are exactly computable projection pairs  $\text{`?+?`}$   $\text{<=> ?`}$ ,  $\text{`? x ?`}$ 
 $\text{<=> ?`}$ ,
 $\text{`? -> ?`}$   $\text{<=> ?`}$  (via `theorem_8_8_b_strong`), so this file only *restates* them under S8.17's
name, and
adds the free bonus corollary `sumUU_trianglelefteq_U`/`prodUU_trianglelefteq_U`/
`funSpaceUU_trianglelefteq_U : (*) ? ?` (Lemma 6.15 applied to those exact pairs).

**Part 3** (a universal domain  $\text{`V`}$   $\text{!= ?`}$ ) is answered in full: Exercise 8.12's  $\text{`V`}$  (a *
different*
`NeighborhoodSystem`, over `Nat` rather than  $\text{`??`}$ 's  $\text{`?`}$ , built from  $\text{`2^kNat+?`}$ ) is effectively
isomorphic
to  $\text{`??`}$  (`effectiveIso812_UV`), hence -- since universality ( $\text{`??`}$ 's defining property, Theorem
8.8(a))
transports along isomorphism --  $\text{`V`}$  is *also* universal (`V_isUniversal`). This needed one
genuinely
new general-purpose tool, **`?` is transitive** (`trianglelefteq_trans`), built by composing

```

```

`ProjectionPair`s (a new `ProjectionPair.comp`, plus `ProjectionPair.ofIso` turning any `
  DomainIso`
into a projection pair via Theorem 2.7's `ofIso`) -- surprisingly, `?'`s transitivity was not
yet in
the codebase despite being an obviously expected structural fact.

**Part 2** (are `?+?`/`? x ?`/`? -> ?` isomorphic to `??`) is **deliberately left open/deferred
** here,
documented rather than guessed at: what we get for free is only the *one-directional*
embeddings
`?+?`, `? x ?`, `? -> ? ?` (bonus corollaries above). Establishing genuine *isomorphism* `?+?` `~=`
`?` (or
`x` `~`) would need a **converse embedding plus a back-and-forth argument** of the same scale as
Exercise
8.12's 7-part, ~2000-line development (`arxiv.md`'s Exercise 8.12 row: "order isos preserve
compactness... so `U ~ V` is not just tedious to build, it needs a genuinely different
technique").
Scott's own parenthetical -- "the author does not know a really good construction for `? -> ?`"
-- flags
that even *he* did not resolve the ` -> ` case; we do not attempt to go further than Scott here
. This is
therefore recorded as a clearly-scoped deferral, not a `sorry`.

Everything proved in this file is **choice-free** (`subseq {propeq, Quot.sound}`) except
where it merely
*mentions* `U`/`V` (which inherit `Classical.choice` from `Definition87.lean`'s `Rat`-order-
instance
provenance, the same footprint as every other `U`-mentioning headline theorem in this project).

# Exercise 8.18 (Scott 1981, PRG-19)

> **Exercise 8.18.** Many of the cases of 8.10 were left unproved. Please establish these
> assertions explicitly.

Recall **Proposition 8.10**: "If `a, b : ? -> ?` are projections, then so are `a+b`, `a x b`,
  and
`a -> b`. If `a` and `b` are finitary, then so are the others; for the fixed-point set of each
  of them
is isomorphic to the corresponding construct applied to the domains determined by `a` and `b`."

## What is formalized here

**Every case of Proposition 8.10 -- for all three combinators `+`, `x`, `->`, in both
  halves -- was
already fully established** by `Proposition810.lean` (`isProjection_sumComb`/`
  isProjection_prodComb`/
`isProjection_arrowComb`, assembled as `isProjection_combinators`) and `Proposition810b.lean`
(`finitaryProjection_sumComb`/`finitaryProjection_prodComb`/`finitaryProjection_arrowComb`,
  plus the
three explicit isomorphisms `sumComb_elementIso`/`prodComb_elementIso`/`arrowComb_elementIso`,
assembled as `finitaryProjection_combinators`). Nothing was left unproved by *this* development
--
Scott's own text left several cases as reader exercises (most likely the `+` and `->` cases,
  which
needed genuinely new `sumMap`/`expMap` bifunctor infrastructure beyond the "obvious" `x` case
  , per
`Proposition810b.lean`'s docstring), but this project closed all of them while proving
  Proposition

```

```

8.10 itself. This file is therefore a pure citation, assembling Proposition 8.10's two
halves
into one headline statement under Exercise 8.18's name -- no new proof content.

Axiom footprint: `subsetq {propeqt, Classical.choice, Quot.sound}`, identical to `
Proposition810.lean`/
`Proposition810b.lean` (the `Classical.choice` is `U`'s own inherited footprint, not new here).

# Exercise 8.19 (Scott 1981, PRG-19)

> Exercise 8.19. Suppose we know both `T` and `E -> E ? E`. Does it follow that `E+E` and
> `E x E ? E`?

Here `T` is the truth-value domain of Example 1.2 (`Example23.T`/`Exercise326.TD`, the same
two-point-plus-bottom domain used throughout S3 for `cond`). Reading "we know `T`" as "we know
`T ? E`" (the natural companion hypothesis to `E -> E ? E`, and exactly what is needed to make
the
argument below go through), the answer is yes, both follow, via two general-purpose `?`

```

constructions:

```

* **Products.** `T ? E` gives an embedding `E x E ? (T -> E)` (pair `(x, y)` up as the
  function
  `t |-> cond(t, x, y)`, using Exercise 3.26's `cond`), and `T ? E` gives `(T -> E) ? (E
  -> E)`
  (precompose with the retraction `E -> T`, contravariant functoriality of `expMap`,
  `Proposition810b.lean`). Chaining with the hypothesis `E -> E ? E` and `?`'s transitivity
  (Exercise 8.17) gives `E x E ? E`.
* **Sums.** `T ? E` similarly gives `E + E ? T x (E x E)` (tag a summand by `which : E+E
  -> T`
  together with the two projections `out_0, out_1 : E + E -> E`, Exercise 3.26's `which`/`
  cond`
  machinery) and `T x (E x E) ? E x (E x E)` (the covariant functoriality of `prod`
  in `T ? E`).
  Composing with `E x E ? E` (just proved, applied twice to peel off the nested product) and
  transitivity gives `E + E ? E`.

```

Both directions reuse only pre-existing combinators (`cond`, `which`, `curry`, `evalMap`,
`expMap`, `paired`/`proj\_0`/`proj\_1`) -- the only genuinely new general-purpose facts are `
expMap`'s
monotonicity in its contravariant argument (`expMap\_mono\_left`), the analogous covariant
monotonicity of pairing (`prod\_left\_triangleleft`/`prod\_right\_triangleleft`), and two small
"cross" round-trip facts for the sum injections (`outMap\_1\_comp\_inMap\_0`/`outMap\_0\_comp\_inMap\_1`
, the
natural companions of Exercise 3.18's `outMap\_0\_comp\_inMap\_0`/`outMap\_1\_comp\_inMap\_1`).

Everything here inherits `Classical.choice` only from `ext\_of\_toElementMap` calls already baked
into `expMap`'s own defining lemmas (`Proposition810b.lean`) and from `T`'s concrete
presentation
(`Example12.lean`) -- the same pre-existing footprint as every other `T`/`cond`-mentioning
theorem
in the project, not something new introduced here.

# Exercise 8.20 (Scott 1981, PRG-19)

> **Exercise 8.20.** For any system we know `D ? D + D`, but what about
>
> `D ? D x D` and `D ? D -> D`?
>
> Would these projections be computable if `D` is effectively given? Are there more than one
> projection pair in each case?

## What is formalized here

```

Both $D \rightarrow D \times D$ and $D \rightarrow (D \rightarrow D)$ hold **unconditionally**, for every domain D (no hypotheses needed, unlike Exercise 8.19's $E \times E \rightarrow E / E + E \rightarrow E$, which genuinely required $T \rightarrow E$ and $E \rightarrow E \rightarrow E$). Both are exhibited by the *simplest possible* combinator recipe, generalized slightly to two (possibly different) domains A , B :

```
* **Products** (trianglelefteq_prod fst / trianglelefteq_prod snd): embed `a |-> <a, False
>` (resp.
`b |-> <False, b>`), retract with `proj_0` (resp. `proj_1`). `proj_0<a,False> = a` on the
nose, and
`<(proj_0 z), False> = <z.fst, False> <= <z.fst, z.snd> = z` since `False <= z.snd`
always
(`Proposition 3.2(i)`'s `pair_le_pair_iff` reduces this to `False <= z.snd`, `
NeighborhoodSystem.bot_le`).
Specializing `A = B = D` gives `D ? D x D` (`D_trianglelefteq_prod`).
* **Function spaces** (trianglelefteq_funSpace_const): embed `b |-> (fun _ . b)` (the
constant function,
`constFunMap := curry (proj_0 B A)`), retract `phi |-> phi(False)` (evaluate at the bottom,
`evalBotMap := evalMap A B comp <id, const False>`). `eval(const_b) = b` on the nose
(`toApproxMap_constFunMap`, from `toElementMap_curry_apply`), and `const_{phi(False)} <=
phi` pointwise
since `phi(False) <= phi(x)` for every `x` by monotonicity of approximable maps**
(`toElementMap_mono`, Proposition 2.2(iii)) applied to `False <= x`. Specializing `A = B =
D` gives
`D ? D -> D` (`D_trianglelefteq_funSpace`).
```

On $D \rightarrow D + D$: Scott states this as *already known* background (not part of the question), so it is not re-derived here. The "easy half" of the projection pair is already in the codebase (`outMap_0_comp_inMap_0`, Exercise 3.18); the second half (`inMap_0_comp_outMap_0 <= id`), needing a case-analysis on general sum elements analogous to the `which`/`condSum` machinery of Exercise 8.19) is genuine additional work that this exercise does not ask for, so it is left as background citation rather than re-proved.

On multiplicity ("are there more than one projection pair"): for products, the two constructions above are already *literally different maps* whenever D has any element $\neq \text{False}$ (`embedFst_ne_embedSnd_of_ne_bot`, by evaluating both at that element and reading off the first coordinate) -- so **yes**, generically more than one. For $D \rightarrow D$, the "evaluate at a fixed point a " half of the recipe is forced to be $a = \text{False}$ (for a *general* a , `const_{phi(a)} <= phi` would need $\text{phi}(a) <= \text{phi}(x)$ for *every* x , i.e. $a <= x$ for every x , i.e. $a = \text{False}$); but distinct projection pairs can still arise by composing this one with any nontrivial order-automorphism of D (if $D \approx ? D$ non-trivially, conjugating `constFunMap`/`evalBotMap` by the automorphism gives a genuinely different pair). We do not formalize this second, automorphism-dependent source of multiplicity here -- it depends on D 's own automorphism group, which is not fixed data for a "for any system" claim -- but record it as the answer to Scott's question.

On computability: every combinator used (`False`, `paired`, `proj_0`/`proj_1`, `curry`, `evalMap`, `constMap`) already has (or, for `constMap` at a fixed computable index such as `False`'s, trivially would have) an `IsComputableMap` closure lemma elsewhere in the project (`proj_0_isComputable`/`proj_1_isComputable`/`paired_isComputable`, `Theorem74.lean`; `curry_isComputable`/`evalMap_isComputable`, `Theorem75.lean`) -- so **yes**, both projection pairs are computable whenever D is effectively given. Assembling the precise numerical parameters these lemmas

```

    expect
    (the `Nat -> Nat` encoding functions `gN`/`incl0`/`incl1`/`eq1` etc.) for *this specific*
    composite is
    extra bookkeeping proportional to a full computable-presentation transport, not to this
    exercise's
    mathematical content, so it is recorded here as a citation-backed answer rather than
    reformatized.

    Everything proved here is **fully choice-free** (`subseq {propeq, Quot.sound}`): following
    the project's
    "prefer `le_iff_toElementMap_le` + `le_antisymm` over `ext_of_toElementMap`" discipline
    (`HANDOFF.md`), even the map *equalities* (`proj_0_comp_embedFst`, `proj_1_comp_embedSnd`,
    `evalBotMap_comp_constFunMap`) are proved via `le_antisymm` on `le_iff_toElementMap_le`-
    unfolded
    goals rather than `ApproximableMap.ext_of_toElementMap`, since both ` $\leq$ `-directions are in
    fact
    trivial (the underlying `toElementMap`s are literally equal, not just comparable) -- so no
    `Classical.choice` is pulled in anywhere, unlike most of `D`-mentioning Exercise 8.19.

> `D_{aS} ~ (D_a)S`.

```

Here `DS` is Scott's tree algebra of Example 6.1 (`Dsharp`, already fully formalized with computable combinators `in`/`pair`/`proj\_0`/`proj\_1` in `Example61.lean`/`Combinators77.lean`/`Exercise717.lean`, and the universal catamorphism `g : DS -> E` of Exercise 7.17 Part 2, `gMap`).

What is formalized here

The construction of `aS`, and the properties that are tractable without new "uniqueness of catamorphism" infrastructure.

* **US ? U** (`dsharpU\_trianglelefteq\_U`): since `dsharpPresentation` (Prop 7.7) makes `US` effectively given, `theorem\_8\_8\_b\_strong` (Theorem 8.8(b)) hands it a *computable* projection pair `iSharp : US -> U`, `jSharp : U -> US` into `U`, exactly as Definition 8.9 fixes `i\_+ / j\_+`,
 i_x / j_x , $i_- \rightarrow j_- \rightarrow$ for $U+U$, $U \times U$, $U \rightarrow U$.

* **The operator itself** (`aSharp`). Scott's recipe for `aS`, read off Example 6.1's own defining equations `out(xS) = x`, `pair(x,y)`, is: recurse `a` on the `D`-summand and leave the tree pairing structure alone, i.e. `aS` should satisfy `aS(xS) = (a x)S` and `aS(<y,z>) = <aS(y), aS(z)>`. But these are *exactly* the two defining equations (`gMap\_in`/`gMap\_pair`) of Exercise 7.17 Part 2's catamorphism `gMap u v` specialized to `u := in` comp `a` and `v := pair` (the tree algebra's own pairing) -- so the "fixed-point construction" the exercise asks for is already on hand as `gMap`, and no new recursion needs to be built:

```
'''
aSharpInner a := gMap (inSharpMap.comp a) pairSharpMap hU : US -> US
aSharp a      := iSharp comp aSharpInner a comp jSharp : U -> U
'''
```

This mirrors Definition 8.9's own conjugation-through-a-projection-pair pattern for `+`, $\times$, $\rightarrow$.

* **Computable** (`aSharp\_isComputable`): `gMap\_isComputable` (the heart of Exercise 7.17 Part 2) applies directly, since `in`/`pair` are computable (`inSharp\_isComputable`/`pairSharp\_isComputable`) and composition of computable maps is computable (`comp\_isComputable`); chaining through `iSharp`/`jSharp`'s own computability (`theorem\_8\_8\_b\_strong`) gives computability of `aSharp a` whenever `a` is computable.

* **`a` <= I ? aS <= I** (`aSharp\_le\_idMap\_of\_le`, half of "`a` a projection ? `aS` a projection", Proposition 8.10's proof recipe `a sqsub I ? a+b sqsub I+I = i comp j sqsub I` transcribed to `S`): the new general tool is **gMap_mono** -- monotonicity of the catamorphism in `u`, `v` -- proved by a direct structural induction on the `GRel` derivation exactly parallel to `gRel\_mono` (Exercise 7.17 Part 2), using that `<= ` on `ApproximableMap` unfolds to pointwise relation inclusion (`ApproximableMap.le\_iff`). Combined with the new characterization **gMap_inSharp_pairSharp_eq_idMap** (`gMap in pair = I\_{DS}`, proved by two structural inductions -- on `GRel` and on `MemS` -- mirroring `gMap\_in`/`gMap\_pair`'s own style) and `comp\_mono\_gen`, monotonicity of `aS` in `a` gives `a <= I -> aS <= I` cleanly.

* **Exercise 8.21(b)** -- the other half of "`a` a projection ? `aS` a projection", idempotence (`a = a comp a ? aS = aS comp aS`). Unlike $x \wedge \rightarrow \wedge \wedge +$ in `Proposition810.lean`, there is no elementwise closed form for `gMap`'s action on a *general* element of `DS` (its elements are potentially *infinite* trees, unlike `pair`/`fst`/`snd` or `curry`/`eval` which have one-step defining equations valid everywhere), so this needs a genuine **uniqueness-of-catamorphism** lemma (`gMap\_eq\_of\_satisfies`: `k` strict, satisfying the two `g`-equations for `(u, v) ? k = gMap u v`)
 -- precisely Scott's own remark in the Example 6.1 discussion ("`g` is unique because the values

```

on finite elements are fixed"), proved by induction on the `MemS`-derivation of the input
neighbourhood (bridging `k`'s abstract relation to the assumed element-level equations via
`rel_iff_mem_principal` and two small "principal of constructor = constructor of principals"
identities, `inSharp_principal`/`pairSharp_principal`). Idempotence of `aSharpInner a`
(`gMap_selfComp_eq_of_isRetraction`, proved in the same general form as the uniqueness lemma)
then
transports through the `US ? U` projection pair exactly as `Proposition810.lean`'s
`isRetraction_prodComb`/`isRetraction_arrowComb` do (`isRetraction_aSharp`), completing
`isProjection_aSharp`: `a` a projection ? `aS` a projection, in full.

* **Exercise 8.21(c) -- the headline isomorphism `D_{aS} ~ (D_a)S`.** The key realization is
that
`D |-> DS` is *functorial* on morphisms, not just on domains: precomposing `inSharpMap`
with any
`f : D' -> D` and recursing via `gMap` (`dsharpMap`) extends `f` to `D'S -> DS`,
satisfying the
functor laws `idS = id` (`dsharpMap_id`, literally `gMap_inSharp_pairSharp_eq_idMap`) and
`(f' comp f)S = f'S comp fS` (`dsharpMap_comp`, via `gMap_eq_of_satisfies` -- verbatim
`gMap_selfComp_eq_of_isRetraction`'s proof, but *without* needing a retraction hypothesis,
since
composing two different maps needs no idempotence). Transporting `iSharp`/`jSharp` through
`dsharpMap`'s action on the injection/projection pair `(fixedNbhd_subsystem a).inj/.proj` of
`D_a := fixedNbhd a ? U` (Proposition 6.12) produces a *new* projection pair
`I : (D_a)S -> U`, `J : U -> (D_a)S` (`ISharpComb`/`JSharpComb`) with `J comp I = I_{(D_a)S}`
(`dsharpMap`'s functor laws applied to `j_a comp i_a = I_{(D_a)}`) and, when `a` is a
finitary
projection, `I comp J = aS` (the functor laws applied to `i_a comp j_a = a`, Theorem 8.6'
s
`inj_comp_proj_eq_self`, noting `aSharpInner a` is literally `dsharpMap` applied to
`i_a comp j_a = a`). `elementIsoOfProjectionPair` (`Proposition810b.lean`) then hands us
`(D_a)S.Element ~ Fix(aS)` directly -- Scott's headline isomorphism, in the same "domain
of a
projection = its `toElementMap`-fixed-point set" convention `Proposition810b.lean` already
uses
for `D_{a+b} ~ D_a+D_b` etc. This also re-proves `IsFinitary (aS)`, so combined with 8.21(
a)/(b)'s
`isProjection_aSharp`, `a` a *finitary* projection of `U` `?` `aS` a finitary projection, in
full.

Axiom footprint: everything here mentions `U`, so (as with `Definition89.lean`/`Proposition810.
lean`)
it inherits `U`'s own `Classical.choice` footprint -- `subseq {propext, Classical.choice,
Quot.sound}`,
confirmed not new; `dsharpMap`/`dsharpMap_id` (mentioning no `U`) are fully choice-free
`subseq {propext, Quot.sound}`, while `dsharpMap_comp` inherits `Classical.choice` from
`gMap_eq_of_satisfies` (matching 8.21(b)'s own baseline, nothing new).

/-! ## Uniqueness of the catamorphism (Exercise 8.21(b), step 1)

Scott's own justification for idempotence-transport ("g` is unique because the values on
finite
elements are fixed") is made precise here: any *strict* map `k : D`S -> E` satisfying the
same two
defining equations as `gMap u v hD` (on the nose, at the *element* level) is literally equal to
it as
an `ApproximableMap`. The proof works with `k`'s neighbourhood relation directly, by induction
on the
`MemS`-derivation of the input neighbourhood `W` -- mirroring `gMap_in`/`gMap_pair`'s own proof
style,
using `rel_iff_mem_principal` to bridge between `k`'s abstract relation and the assumed *
element*-level
equations at the principal element of each `MemS`-shape. Two small "principal of the
constructor is
the constructor of principals" identities do the bridging work (`inSharp_principal`,
`pairSharp_principal`); the general `pair_principal_eq_principal_prodNbhd` (about `prod`, not
`Dsharp` specifically) underlies the second one. -/

/-- **`<P, Q> = (P U Q)`** (general, for any two neighbourhood systems): the pairing of two
principal elements is the principal element of the product neighbourhood. -/
theorem pair_principal_eq_principal_prodNbhd {? ? : Type*} {V_0 : NeighborhoodSystem ?}

/-- **Uniqueness of the catamorphism** (Exercise 8.21(b)(1), Scott's own remark "`g` is unique
because the values on finite elements are fixed"). Any *strict* `k : DS -> E` satisfying `
gMap`s two
defining equations at the *element* level -- `k(xS) = u(x)` and `k(<y,z>) = v(<k(y),k(z)>)` --
is
literally the catamorphism `gMap u v hD`. Proved by induction on the `MemS`-derivation of the
input
neighbourhood, generalizing over the output: the `Gamma` case is strictness plus `master_rel`;
the leaf
case reads the hypothesis off at the principal element `X` via `inSharp_principal` and
`rel_iff_mem_principal`; the node case does the same with `pairSharp_principal`, using the
induction
hypotheses to identify the two recursive outputs. -/

/-! ## Exercise 8.21(c): $D_{\{a\}} \simeq (D_a)^S$

For a *finitary projection* a of U , transport $iSharp$ / $jSharp$ through $dsharpMap$'s functorial action on the injection/projection pair $(fixedNbhd_subsystem\ a).inj/.proj$ of $D_a := fixedNbhd\ a\ ?\ U$ (Proposition 6.12), producing a genuine projection pair $I : (D_a)^S \rightarrow U$, $J : U \rightarrow (D_a)^S$. The functor laws $dsharpMap_id$ / $dsharpMap_comp$ turn $j_a\ comp\ i_a = I_{\{D_a\}}$ (Proposition 6.12's own $proj_comp_inj$) into $J\ comp\ I = I_{\{D_a\}}^S$

immediately, and $i_a\ comp\ j_a = a$ (Theorem 8.6's $inj_comp_proj_eq_self$, using that a is finitary projection) into $I\ comp\ J = a^S$ -- exactly $aSharp$'s own definition, once one notices

$aSharpInner\ a$ is literally $dsharpMap$ applied to $i_a\ comp\ j_a = a$. $elementIsoOfProjectionPair$ (Proposition810b.lean) then hands us the isomorphism directly, in

the same "domain of a projection = its $toElementMap$ -fixed-point set" convention already used throughout Proposition810b.lean for $D_{\{a+b\}} \simeq D_a + D_b$ etc. -/

# Exercise 8.22 (Scott 1981, PRG-19, S8) -- `B ? C`, `C ? B`, and general domain equations

> **EXERCISE 8.22.** Which of the two relations hold: `B ? C` or `C ? B`? Or do they both hold?
  In
> general if we use domain equations `D = T(D) + S(D)` and `E = T(E)`, will `E ? D` hold? What
> projections do you see in the examples in 6.2?

Scott's staple examples of Example 6.2 satisfy `B = B + B` and `C = ? + C + C`, both
presented over
the same token type `Str = List Bool` as the least families

`B = {Sigma*} U {0X ? X in B} U {1X ? X in B}`, `C = {Sigma*} U {{sigma} ? sigma
  in Sigma*} U {0X ? X in C} U {1X ? X in C}`,

i.e. `memB X <=> exists sigma, X = cone sigma` and `memC X <=> (exists sigma, X = cone
  sigma) /\ (exists sigma, X = {sigma})` (`ExampleB.lean`,
`Example44.lean`). **Both `B ? C` and `C ? B` hold** -- so the answer to "or do they both hold
  ?" is
*yes*.

## `B ? C` -- the direct projection ("what projections do you see in the examples in 6.2")

Since `B` and `C` are literally systems over the same tokens with `B.mem subseteq C.mem` (
  every
  `B`-neighbourhood `cone sigma` is already a `C`-neighbourhood), `B` is a literal subsystem
  of `C`
in the sense of Definition 6.10: `B ? C`. The only content is the `inter_closed` clause, which
  is
  immediate from `cone_trichotomy` (two `B`-neighbourhoods are nested or disjoint; disjoint is

```

excluded because we're assuming the intersection is a nonempty C -neighbourhood). Proposition 6.12 then hands us the projection pair: $i : B \rightarrow C$ the identity inclusion, $j : C \rightarrow B$ the "collapse extra completions back onto the enclosing cone" retraction -- exactly the projection Scott is asking us to notice in Example 6.2.

$C \rightarrow B$ -- a genuine combinatorial embedding

This is the more interesting direction, since C has "extra" elements -- the completed finite sequences $\text{strElem } \sigma = \{\sigma\}$ -- that are not present at all in B (every B -element is either an infinite sequence or a *properly extendable* partial one; B has no isolated/maximal element at a finite position). Nonetheless C embeds into B via a concrete, choice-free re-encoding of tokens that never needs to leave the finite-string world:

```
* **`enc : Str -> Str`** doubles every bit (`enc [] = []`, `enc (b :: sigma) = b :: b :: enc sigma`), so
`enc` is injective, monotone, and *prefix-reflecting* (`enc_prefix_iff : enc sigma <+: enc tau <-> sigma <+: tau`)
-- it re-encodes `C`'s "still going" positions (`cone sigma`) as `B`-cones `cone (enc sigma)`
.
* **`encC sigma := enc sigma ++ [true, false]`** appends the two-bit marker `[true, false]`,
which can
*never* be confused with a doubled block `[b, b]` (`b = b` always, `true != false`) -- this
re-encodes `C`'s "completed" positions (`{sigma}`) as a *further, deeper* `B`-cone `cone (encC sigma)`
that just happens to never get extended any further inside the image subsystem `D`. The
hard-won combinatorial facts (`enc_prefix_encC_iff`, `encC_prefix_encC_iff`,
`not_encC_prefix_enc`) show this re-encoding exactly reproduces `C`'s own nesting/
disjointness
pattern of cones vs. singletons, all via ordinary structural induction on `Str` (no
infinitary
or choice machinery needed).
* **`D' : NeighborhoodSystem Str`** is the subfamily `{cone (enc sigma)} U {cone (encC sigma)}`
of `B`'s
cones. Since *every* `D`-neighbourhood is already a `B`-cone, `NestedOrDisjoint memD'` is
free
from `B`'s own `cone_trichotomy` (`D'_nestedOrDisjoint`), and `D' ? B` follows just as easily
(`D'_subsystem_B`).
* **`toD'`/`fromD'`** transport `C`'s elements to `D`'s elements and back (mirroring
`Example62.toBB`/`fromBB`), giving the order-isomorphism `cdEquiv : C.Element ?o D'.Element`
hence `C ~?= D'`, and with `D' ? B` this is exactly `C ? B` (`Lemma615.Trianglelefteq`).
```

The general question: $D = T(D) + S(D)$, $E = T(E)$ -- will $E ? D$?

Instantiating $T(X) := X + X$, $S(X) := ?$: $B \approx T(B)$ and $C \approx T(C) + S(C)$, so B plays the role of E and C plays the role of D -- and indeed $B ? C$ holds, as shown above. This matches the general categorical picture (a direct generalization of Theorem 6.16's embedding argument): the sum decomposition $D \approx T(D) + S(D)$ always gives a **projection pair** $T(D) ? D$ (project the $S(D)$ summand to the fresh bottom), not merely an *embedding* $T(D) ? D$; running Theorem 6.16's own approximant-chain construction with this projection pair standing in for D 's Lambek isomorphism (in place of the *full* isomorphism the original theorem uses) produces, from E 's own iso $T(E) \approx E$ and E 's initiality, a genuine projection pair $E \leq D$, hence $E ? D$ -- reusing exactly

```

the ladder/fixed-point machinery of `Theorem616.lean` with one side weakened from an
    isomorphism to
a retraction. We do not carry out this re-derivation in Lean here (it would essentially
    duplicate
`Theorem616.lean`'s ~250 lines with one hypothesis weakened); the concrete instance for `B`, `C`
    above is a full, formally checked confirmation of the pattern the general argument predicts.

Everything proved here is choice-free (`#print axioms subseq {propext, Quot.sound}`).

# Exercise 8.23 (Scott 1981, PRG-19, S8) -- the fixed-point method really does solve `D ~?= T(
D)`

> **EXERCISE 8.23.** Suppose a construct `T` on domains can be made into a computable operator
> `t : (U -> U) -> (U -> U)` so that whenever `a : U -> U` is a finitary projection,
> then so is `t(a)`
> and `D_{t(a)} ~?= T(D_a)`. Does it follow that `?t? = fix(t)` is such that `D_{?t?} ~?= T(
D_{?t?})`
> really is the initial solution of the domain equation with respect to projections? Since `t`
> is
> computable, will this solution be effectively given?

**Answer: yes to all three questions.** This file formalizes the two purely order-theoretic
claims in full (working over an *arbitrary* neighbourhood system `E` in place of `U` -- nothing
in

```

the argument is specific to the universal domain), and explains the computability claim in prose, matching this codebase's existing precedent (Theorem 8.6's own computability clause, ``sub``'s Clause 3, is likewise deferred: computability needs ``E`` effectively given, Definition 7.1 machinery, a separate prerequisite not otherwise used here).

Setup: ``t`` as a self-map of the function space, ``tOp`` as the induced operator on maps

Scott's ``t : (U -> U) -> (U -> U)`` is modelled as an approximable **self-map** of the function space

```
`t : ApproximableMap (funSpace E E) (funSpace E E)`
```

(matching how ``Theorem86.lean``'s ``subApprox` itself is built) -- an *element* of ``funSpace E E`` is (via ``Theorem 3.10``'s ``funSpaceEquiv``) literally a filter representation of an approximable map ``E -> E``, so a continuous self-map of ``funSpace E E`` is exactly Scott's "computable operator on ``(E -> E)``" (dropping "computable" to "approximable", since only Theorem 4.1's *existence* of a fixed point is used for the two claims proved here). The induced operator on actual maps is ``tOp t a := toApproxMap (t.toElementMap (toFilter a))``, and ``?t? := fixOp t := toApproxMap (Theorem 4.1's `t.fixElement`)`` is Scott's ``fix(t)``.

Claim 1 -- ``?t?`` really is a finitary projection (``isFinitaryProjection_fixOp``)

This is the crux, and is proved by an elegant chase through **Theorem 8.6's ``sub`` combinator** rather than by re-deriving any of Theorem 6.16's heavy `?-colimit-of-domains` machinery:

- * ``sub f = f <-> IsFinitaryProjection f`` (Theorem 8.6(a)) turns "is a finitary projection" into a purely equational condition.
- * By induction on ``n``, every approximant ``t.iterElem n`` (Theorem 4.1(iii)'s chain ``t?(False)``) is, under ``toApproxMap``, a finitary projection: the base case ``n = 0`` is the constant-bottom map ``constMap E E.bot`` (shown finitary projection directly: idempotent and ``<= I`` by bare unfolding; finitary because its fixed-point set is the singleton ``{False}``, order-isomorphic to the terminal system ``?`` = ``unitSys``); the step case is exactly hypothesis ``ht``.
- * Hence every ``t.iterElem n`` is a fixed point of ``sub``, i.e. of ``subFilter`` (``sub`` transported to ``funSpace E E``'s own elements, Theorem 8.6(b)).
- * **The key fact**, already on hand in ``Theorem86.lean``: ``subFilter`` commutes with directed unions (``Sub8_6.subFilter_iSupDirected``), because ``sub``'s defining formula is a *positive existential* in the map's relation. Since ``?t?``'s underlying element ``t.fixElement = sqsup _n t.iterElem n`` (Theorem 4.2(iii)) and ``subFilter`` fixes every term of this directed union, ``subFilter`` fixes the union itself -- i.e. ``sub ?t? = ?t?``, giving ``IsFinitaryProjection ?t?`` right back out of Theorem 8.6(a).

This sidesteps entirely the delicate "colimit of finitary domains is finitary" argument Theorem 6.16 needs in the general categorical setting -- here it is a two-line consequence of ``sub`` already being known to be *continuous* on the function space.

Claim 2 -- ``D_{?t?} ~ T(D_{?t?})``, and ``?t?`` is initial with respect to projections

``?t?`` is not merely an *approximate* limit of the chain -- Theorem 4.1 makes it a *genuine* fixed

point: $\text{tOp } t \text{ (fixOp } t) = \text{fixOp } t \text{ (}\text{tOp_fixOp}\text{, from }\text{toElementMap_fixElement}\text{)}$. Consequently, whatever abstract correspondence T the hypothesis packages (modelled here as a function T from maps to Σ -bundled domains, with $\text{hT } a : \text{Fix}(\text{tOp } t \text{ } a) \sim T(a)$ for every finitary projection a), instantiating at $a := ?t?$ and rewriting $\text{tOp } t \text{ (} ?t? \text{)} = ?t?$ on the nose gives $\text{Fix}(?t?) \sim T(?t?)$ unconditionally** (`fixedDomain_fixOp_iso_T`) -- *not* an approximate/colimit argument, a literal substitution, precisely because $?t?$ solves the equation exactly rather than in the limit.

Initiality with respect to projections (`fixedNbhd_fixOp_subsystem`): if a is *any* other finitary projection that is a pre-fixed point of the same operator ($\text{tOp } t \text{ } a \leq a$ -- covering, in particular, every *exact* alternative solution $\text{tOp } t \text{ } a = a$), then Theorem 4.1's minimality (`fixElement_le_of_toElementMap_le`) gives $?t? \leq a$, and Exercise 8.16's order-isomorphism $a \leq b \iff D_a \leq D_b$ upgrades this to $D_{?t?} \leq D_a$ (hence certainly $D_{?t?} \leq D_a$, Lemma 6.15) -- exactly Scott's "initial solution with respect to projections".

Claim 3 -- effectively given if t is computable (not formalized: prose only)

Scott's own text leaves the *computability* clause of the closely analogous Theorem 8.6 (`sub` is a computable, finitary projection when E is effectively given) unformalized in this codebase for the same reason: it needs Definition 7.1's `ComputablePresentation` machinery threaded through a directed *union* of presentations, not merely a single presentation. The expected argument (fully analogous to Theorem 8.8(b)'s computable back-and-forth and Theorem 8.8(c)'s `fixedNbhd_isEffectivelyGiven`, both already in this codebase) is: since t is computable and $E.\text{bot}$ is (trivially) computable, every approximant $t.\text{iterElem } n$ is computable by a routine induction (composition of computable maps is computable); the union defining $?t?$ is then a *recursively enumerable* union of computable approximants -- indexed by $n : \text{Nat}$, decidable increasing -- hence $?t?$ itself is computable by the standard "effective limit of an effective chain" argument (the same style of argument `Theorem88b.lean` -- `Theorem88m.lean` already carry out for the *other* effective limiting construction in this book, Theorem 8.8's back-and-forth Y_n -chain). We do not carry this out in Lean here, matching the `sub`-computability precedent.

Everything **proved** in this file (Claims 1-2) is **choice-free** (`#print axioms subseq {proptext, Quot.sound}`).

# Exercise 8.24 (Scott 1981, PRG-19, S8) -- mutual fixed points really do solve `D ~ S(D,E)`,
`E ~ T(D,E)`

> **EXERCISE 8.24.** Suppose `S` and `T` are two (binary-argument) constructs on domains that
can
> be made into computable operators on projections of the universal domain. Show that we can
> therefore find a pair of effectively presented domains such that `D ~ S(D, E)` and `E ~ T(D, E)`.

**Answer: yes. This is the two-variable (mutual-recursion) generalization of Exercise 8.23,
and
the whole argument reduces to a single instance of Exercise 8.23's own machinery, applied not
to
`(E -> E)` but to the **product** function space `(E -> E) x (E -> E)` -- Scott's pairs
`(a, b)` of
self-maps of `E`. Formalized here (again over an arbitrary neighbourhood system `E`, not just `U`)
for the two purely order-theoretic claims, with the computability clause deferred to prose,
exactly
matching Exercise 8.23's own precedent.

## Setup: `s, t` as approximable maps out of the pair space, `paired s t` as the combined
operator

Scott's two operators `s, t : (E -> E) x (E -> E) -> (E -> E)` are modelled as
approximable maps out of

```

the **pair space** `PairSpace := (funSpace E E) x (funSpace E E)` (Lecture III's `prod`) into the single function space `funSpace E E`:
`s t : ApproximableMap PairSpace (funSpace E E)`. The induced operators on actual map-pairs are `binOp s a b := toApproxMap (s.toElementMap (pair (toFilter a) (toFilter b)))` (Scott's `s(a, b)`), and likewise `binOp t a b` (Scott's `t(a, b)`).

The two operators combine into a **single self-map** of the pair space, `paired s t : ApproximableMap PairSpace PairSpace` (Definition 3.3's pairing combinator: `<s, t>(z) = <s(z), t(z)>`), to which Theorem 4.1 applies exactly as in Exercise 8.23. Its exact fixed point `(paired s t).fixElement : PairSpace.Element` splits, via Definition 3.1's projections `.fst`/`.snd`, into the two components `aStar s t := toApproxMap (paired s t).fixElement.fst` and `bStar s t := toApproxMap (paired s t).fixElement.snd` -- Scott's simultaneous solution `(?s?, ?t?)` of the mutual recursion.

The approximants `(paired s t).iterElem n` similarly split into chains `aOp s t n`/`bOp s t n` (`.fst`/`.snd` again), satisfying the expected mutual recursion `aOp s t (n+1) = binOp s (aOp s t n) (bOp s t n)`, `bOp s t (n+1) = binOp t (aOp s t n) (bOp s t n)` (`aOp_succ`/`bOp_succ`), with base case the constant-bottom map on both sides (`aOp_zero`/`bOp_zero`, reusing Exercise 8.23's `isFinitaryProjection_constMap_bot`).

Claim 1 -- `aStar s t`, `bStar s t` really are finitary projections (`isFinitaryProjection_aStar_bStar`)

Given `hst : forall a b, IsFinitaryProjection a -> IsFinitaryProjection b -> IsFinitaryProjection (binOp s a b)` / `IsFinitaryProjection (binOp t a b)` (Scott's hypothesis that `s`/`t` send pairs of projections to projections), an induction using `aOp_succ`/`bOp_succ` shows every approximant pair `(aOp s t n, bOp s t n)` consists of finitary projections, exactly as in Exercise 8.23's Claim 1.
The genuinely new step is transporting Theorem 8.6's `sub`/`subFilter` continuity-with-directed-sups argument through the `.fst`/`.snd` projections: `(paired s t).fixElement.fst` is identified with the directed union `sqsup_n (aOp s t n)`'s underlying filter (`hEqA`, a direct membership chase through `mem_fst`/`mem_fixElement`/`mem_iterElem`, paralleling `Theorem41.fixElement_eq_iSupDirected` one level down through the product), and `subFilter` fixes it termwise, hence fixes the union (`hkeyA`/`hkeyB`, `Sub8_6.subFilter_iSupDirected`) -- verbatim Exercise 8.23's Claim 1 argument, just run twice (once per component).

Claim 2 -- `Fix(aStar s t) ~ S(aStar s t, bStar s t)`, `Fix(bStar s t) ~ T(aStar s t, bStar s t)`, and initiality with respect to projections

`(aStar s t, bStar s t)` is a *genuine* (not merely approximate) simultaneous fixed point: `binOp s (aStar s t) (bStar s t) = aStar s t` and likewise for `t` (`binOp_aStar_bStar_left/right`), from `toElementMap_fixElement` (Theorem 4.1) plus `toElementMap_paired`/`.fst_pair`/`.snd_pair`/`pair_fst_snd` bookkeeping -- again a bare substitution, not a colimit argument. Substituting `a := aStar s t`, `b := bStar s t` into an abstractly-packaged pair of hypotheses `hS a b : Fix (binOp s a b) ~ S(a,b)`, `hT a b : Fix (binOp t a b) ~ T(a,b)` (Scott's `D_{s(a,b)}` ~ `S(D_a, D_b)`, `D_{t(a,b)}` ~ `T(D_a, D_b)`, packaged directly in terms of the maps `a`, `b` as in Exercise 8.23) and rewriting the two equations gives `Fix(aStar s t) ~ S(aStar s t, bStar s t)` and `Fix(bStar s t) ~`

```

T(aStar s t, bStar s t) `**unconditionally** (`fixedDomain_aStar_bStar_iso`) -- exactly Scott's
`D ~ S(D, E)`, `E ~ T(D, E)`, with `D := Fix(aStar s t)`, `E := Fix(bStar s t)`.

**Initiality with respect to projections** (`fixedNbhd_aStar_bStar_subsystem`): if `a, b` is *
any*
other pair of finitary projections that is a pre-fixed point of the same pair of operators
(`binOp s a b <= a`, `binOp t a b <= b`), then packaging `(a, b)` as `pair (toFilter a) (
toFilter b)` :
PairSpace.Element`, the pre-fixed-point hypotheses assemble (via `pair_le_pair_iff`) into a
single
pre-fixed-point inequality for `paired s t`, so Theorem 4.1's minimality
(`fixElement_le_of_toElementMap_le`) gives `(paired s t).fixElement <= pair (toFilter a) (
toFilter
b)`; taking `.fst`/`.snd` and transporting through Exercise 8.16's order-isomorphism `a <= b
<-> D_a ?
D_b` gives `fixedNbhd (aStar s t) ? fixedNbhd a` and `fixedNbhd (bStar s t) ? fixedNbhd b` --
Scott's
"the initial solution... with respect to projections", now for *both* components simultaneously
.

## Claim 3 -- effectively given if `s, t` are computable (not formalized: prose only)

Exactly Exercise 8.23's own deferred computability clause, doubled: if `s` and `t` are
computable
(relative to a `ComputablePresentation` of `E`'s function space), then `constMap E E.bot` is
trivially computable, and by a routine joint induction every approximant pair `(aOp s t n, bOp
s t
n)` is computable (composition/pairing of computable maps is computable -- `binOp`'s definition
is
literally `toElementMap` applied to a `pair`, both computable operations). The simultaneous
limit
`(aStar s t, bStar s t)` is then a recursively-enumerable union of computable approximant pairs
,
indexed by `n : Nat`, hence computable by the same "effective limit of an effective chain"
argument
already carried out in this codebase for Theorem 8.8's back-and-forth `Y_n`-chain
(`Theorem88b.lean`-`Theorem88m.lean`). Not carried out in Lean here, matching the `sub`- and
Exercise-8.23-computability precedents.

Everything **proved** in this file (Claims 1-2) is **choice-free**
(`#print axioms subseq {propeq, Quot.sound}`).

# Exercise 8.25 (Scott 1981, PRG-19, S8), obstruction -- `?` -> `? = ?`

Scott's exercise asks first to notice that the "obvious" solution of `D ~> D -> D` by
retracts of the
universal domain `?` is of no use, because `1 -> 1 = 1` for projections: the only finitary
projection whose fixed-point domain is the terminal one-point domain `?` is (up to the trivial
retract structure) itself again `?`, so iterating the "solve `D ~> D -> V`" method starting
from the
smallest possible `V = ?` produces nothing but `?` again -- the recursion is stuck at the
bottom of
the lattice of projections and never escapes to a non-trivial domain.

This file records the precise domain-level fact behind Scott's remark: `?` is a fixed point of
the
function-space construction, `(? -> ?) ~> ?`. Both `?`'s own element poset and the poset of
approximable self-maps of `?` are one-point (`Unique`), and any two `NeighborhoodSystem`s whose
element posets are both `Unique` are trivially isomorphic (`isoOfUnique`) -- there is only one

```

order-isomorphism type on a singleton. This is exactly why Scott says the naive approach is "of no use": solving $D \simeq D \rightarrow ?$ by the fixed-point method (Exercise 8.23, with $T(a) := ?$ constantly) would converge to $D = ?$, which trivially satisfies $? \simeq ? \rightarrow ?$ but carries no information -- hence Scott's instruction to "change the method", starting instead from the much larger $?^? \inf _$ in place of $?^?$.

Everything here is **choice-free** (`#print axioms subsetting {proptext, Quot.sound}`): the only inputs are `Unique`/`Subsingleton`` reasoning and the existing `funSpaceEquiv`` bijection.

# Exercise 8.25 (Scott 1981, PRG-19, S8), toolkit -- function-space congruence and currying

Two small general-purpose isomorphism-manipulation tools, needed to assemble the final closing
argument of Exercise 8.25 ( $D \simeq D \rightarrow V$ ,  $V \times V \simeq V \rightarrow D \times D \simeq D$ ,  $D \simeq D \rightarrow D$ ):

* funSpace_congr:  $?_0 \simeq ?_0'$ ,  $?_1 \simeq ?_1'$   $\Rightarrow$   $(?_0 \rightarrow ?_1) \simeq (?_0' \rightarrow ?_1')$ , built from
  Proposition810b.lean's Hom-bifunctor expMap (f |→ k comp f comp h) applied to the
  two ApproximableMap's
  ofIso e_0.symm/ofIso e_1 coming from the given order-isomorphisms, using expMap's
  functor laws
  (expMap_comp/expMap_id) to see that the two induced maps are exact mutual inverses
  (orderIsoOfMutualInverse, a small standalone gadget: two approximable maps composing to the
  identity on the nose in both directions give an order-isomorphism of element types --
  arguably
  missing general infrastructure, provided here).
* curry_isomorphic:  $(?_0 \times ?_1 \rightarrow ?_2) \simeq (?_0 \rightarrow (?_1 \rightarrow ?_2))$ , Theorem
  3.12's curryIso
  (Table55.lean) restated as a domain isomorphism.

Everything is choice-free (#print axioms subseq {propext, Quot.sound}).

# Exercise 8.25 (Scott 1981, PRG-19, S8), toolkit -- the abstract closing argument

Scott's hint chain for a *non-trivial* solution of  $D \approx D \rightarrow D$  ends with an abstract
algebraic
step, isolated here from the concrete construction of  $D$  and  $V = ?^\infty$ : given

*  $hDV : D \approx D \rightarrow V$  (a solution of the *auxiliary* equation, e.g. via Exercise823's
fixed-point
machinery with  $V = ?^\infty$ ), and
*  $hVV : V \times V \approx V$  (e.g. Exercise825Pow.pow_prod_isomorphic),

conclude first prod_self_isomorphic : D x D ≈ D and then
funSpace_self_isomorphic : D ≈ D → D.

The argument (all isomorphisms, no fixed-point theory needed at this level):

...
D x D ≈ (D → V) x (D → V) [hDV.prod hDV]
≈ D → (V x V) [funProd_isomorphic, reversed]
≈ D → V [funSpace_congr_right hVV]
≈ D [hDV.symm]
...

and then, reusing prod_self_isomorphic : D x D ≈ D,

...
D → D ≈ D → (D → V) [funSpace_congr_right hDV]
≈ (D x D) → V [curry_isomorphic, reversed]
≈ D → V [funSpace_congr_left prod_self_isomorphic]
≈ D [hDV.symm]
...

```

(so $D \approx D \rightarrow D$ is the `.symm` of this last chain).

Everything is stated for abstract D , V , so it applies verbatim once the concrete D (solving $D \approx D \rightarrow ?^{\text{inf}}$) and $V := ?^{\text{inf}}$ are in hand.

Everything is `**choice-free modulo ApproximableMap.ext_of_toElementMap**`
`(#print axioms subseteq {propext, Classical.choice, Quot.sound}`, matching funSpace_congr`'
s budget).

`import Scott1980.Neighborhood.Exercise316`
`import Mathlib.Logic.Equiv.Nat`

`/-!`

`# Exercise 8.25 (Scott 1981, PRG-19, S8), step 2 --  $?^{\text{inf}} \times ?^{\text{inf}} \approx ?^{\text{inf}}$`

Scott's hint asks us to first establish $?^{\text{inf}} \times ?^{\text{inf}} \approx ?^{\text{inf}}$, where $?^{\text{inf}}$ is the countable power of the universal domain $?$ with itself. We take $?^{\text{inf}} := \text{iterSys } ?$ (Exercise 3.16's infinite iterate, already available with a full API: `iterSeqEquiv`, `iter_isomorphic`, `projN`, effective givenness).

```

The isomorphism  $\sum x \times \sum y \simeq \sum (x \times y)$  is the domain-level shadow of the classical
fact that a pair of
sequences can be interleaved into a single sequence without loss of information:  $\text{Nat} \times \text{Nat} \simeq \text{Nat}$ 
(Equiv.natSumNatEquivNat) reindexes  $(\text{Nat} \rightarrow E) \times (\text{Nat} \rightarrow E) \simeq (\text{Nat} \times \text{Nat} \rightarrow E)$ 
 $\simeq (\text{Nat} \rightarrow E)$  for any
preordered  $E$ , order-isomorphically. Transporting along iterSeqEquiv turns this into
 $(\text{iterSys } V).\text{Element } x \times (\text{iterSys } V).\text{Element } y \simeq (\text{iterSys } V).\text{Element } z$  for any  $V$ , i.e.
 $\text{iterSys } V \times \text{iterSys } V \simeq \text{iterSys } V$ . Specializing  $V := \mathbb{N}$  gives the required  $\sum x \times \sum y \simeq \sum (x \times y)$ .

import Scott1980.Neighborhood.Lemma615

/-!
# Exercise 8.25 (Scott 1981, PRG-19, S8), step 3 -- `? ? ?^ inf`

Scott's hint remarks that (after solving `D ~ = D → ?^ inf`) "`? ? D`", i.e. the universal
domain `?`
embeds as a subdomain of the solution `D`, which is what makes the eventual `D` non-trivial and
universal. The link runs through `? ? ?^ inf` : any domain `V` embeds into its own infinite
power
`V^ inf = iterSys V` as the "singleton stack" `x |→ <x, False, False, ...>`, with `head` as
a retraction.

This file proves `V ? iterSys V` for every `V` (Lemma 6.15 applied to the projection pair
`embedIntoPow dashv head`), reusing the stack combinators `head`/`push`/`pair` from Exercise
5.11 and
the bottom-sequence computation `component_bot` from Exercise 6.18. Specializing `V := ?` gives
Scott's `? ? ?^ inf`.

Everything is choice-free (`#print axioms subseq {propext, Quot.sound}`).

Exercise 8.25 (Scott 1981, PRG-19, S8), step 3 -- solving $D \simeq D \rightarrow ?^{\infty}$ by the fixed-point method

Scott's hint: solve $D \simeq D \rightarrow ?^{\infty}$ "using the methods of Exercise 8.23". This file supplies the one remaining ingredient `Exercise825Closing.lean` needs: a concrete D with $D \simeq D \rightarrow V$ for

$V := \text{iterSys } ? = ?^{\infty}$.

Strategy

Exercise 8.23's abstract machinery (`Exercise823.isFinitaryProjection_fixOp`, `Exercise823.fixedDomain_fixOp_iso_T`) turns "a continuous operator $t : (? \rightarrow ?) \rightarrow (? \rightarrow ?)$ sending finitary projections to finitary projections, with $\text{Fix}(t(a)) \simeq T(a)$ " into a genuine solution $D_{\{t?\}} \simeq T(t?)$. We instantiate $T(a) := D_a \rightarrow D_c$ (Proposition 8.10(b)'s $\rightarrow$ -case) for a $*\text{fixed}*$ finitary projection $c : ? \rightarrow ?$ with $\text{Fix}(c) \simeq ?^{\infty}$, so $t(a) := a \rightarrow c = \text{arrowComb } a \ c$ (a varying, c fixed) and $T(t?) = D_{\{t?\}} \rightarrow D_c \simeq D_{\{t?\}} \rightarrow ?^{\infty}$.

Building c with $\text{Fix}(c) \simeq ?^{\infty}$

$?^{\infty} = \text{iterSys } ?$ is effectively given (`Exercise715.iterSys_isEffectivelyGiven`), so Theorem 8.8(b)'s `theorem_8_8_b_strong` gives a projection pair $i : ?^{\infty} \rightarrow ?$, $j : ? \rightarrow ?^{\infty}$ with $j \text{ comp } i = I$ and $i \text{ comp } j \leq I$. Setting $c := i \text{ comp } j$, Proposition 8.10(b)'s generic `elementIsoOfProjectionPair`/`isFinitary_of_projectionPair` machinery gives `IsFinitaryProjection c` and $?^{\infty} \simeq \text{Fix}(c)$ directly (`cElementIso`), and combined with `Proposition82.elementIso` applied to `fixedNbhd c ? ?` (Theorem 8.5/8.6's usual bridge, `inj_comp_proj_eq_self`) gives `fixedNbhd c \simeq ?^{\infty}` (`fixedNbhd_cCombinator_isomorphic`).

Building t as a genuinely continuous self-map of $\text{funSpace } ? ?$

This is the technical crux: $a \mapsto \text{arrowComb } a \ c$ must be $*\text{continuous}$ in a (an element of $\text{funSpace } ? ?$), not just a family of maps indexed by a . We build it from Table 5.5's `compC`

`curryC`/`evalC` combinators via a joint three-variable evaluator

$R(\psi, \phi, x) := c(\phi(\psi(x)))$, ψ, ϕ in $? \rightarrow ?$, x in $?$,

purely as a composite of `evalMap`/`proj`/`paired`/`comp` (`RMap`) -- manifestly continuous jointly

in all three arguments since `evalMap` itself is. Currying `R` twice (`curryOnceC`), then

```

`curryC`, giving `lamOp c : (? -> ?) -> ((? -> ?) -> (? -> ?))`, an element of a fourth-
order function
space) recovers Definition 8.9's `lamComb a c = expMap a c` at each fixed `a` (`
toApproxMap_lamOp`,
checked against `Proposition810b.toApproxMap_toElementMap_expMap`). Composing on the outside
with
the *fixed* Hom-functor action `expMap jArrow iArrow` (conjugating by the fixed projection pair
`? <=> (? -> ?)` produces `t := tOpMap c`, and unwinds to exactly `arrowComb a c` at every `
a`
(`tOp_tOpMap`) -- so `t` really is Definition 8.9's `arrowComb (-) c`, made continuous.

## Assembling the theorem

`ht_tOpMap` transports Proposition 8.10(b)'s `finitaryProjection_arrowComb` along `tOp_tOpMap`
to
get Exercise 8.23's hypothesis; `Exercise823.isFinitaryProjection_fixOp` and
`Exercise823.fixedDomain_fixOp_iso_T` (instantiated at `T(a) := funSpace (fixedNbhd a)
(fixedNbhd c)`, via `arrowComb_elementIso`) hand us `D ~ D -> (fixedNbhd c) ~ D -> ?`
inf ` for
`D := fixedNbhd (fixOp t)` (`Dsol_isomorphic_funSpace_cCombinator`). Combined with
`Exercise825Pow.pow_prod_isomorphic` (transported along `fixedNbhd c ~ ?` inf `, giving
`hVV_cCombinator : (fixedNbhd c) x (fixedNbhd c) ~ fixedNbhd c`), `Exercise825Closing`'s
abstract
closing argument finishes: `D ~ D -> D` (`exercise_8_25_main`).

**Non-triviality/universality** (`U_trianglelefteq_Dsol`): chaining `? ? ?` inf `
(`Exercise825Embed.trianglelefteq_iterSys`), `?` inf ~ fixedNbhd c` (hence `?`), the *
general* fact
`? ? (? -> ?)` (`Exercise820.trianglelefteq_funSpace_const`, the constant-function embedding)
at
`? := fixedNbhd c`, `? := D`, and `D -> (fixedNbhd c) ~ D` (from `
Dsol_isomorphic_funSpace_cCombinator`,
reversed) gives `? ? D`: the solution domain genuinely contains a copy of the universal domain
`?`,
so it is non-trivial (matching Scott's remark).

Axiom footprint: everything here mentions `U`, so -- like `Definition89.lean`/`Proposition810b.
lean`
-- it inherits `U`'s own `Classical.choice` footprint (`subseq {propext, Classical.choice,
Quot.sound}`),
confirmed not new.

# Exercise 8.25 (Scott 1981, PRG-19, S8) -- a non-trivial domain isomorphic to its own function
space

> **EXERCISE 8.25.** Give an example of a *non-trivial* domain `D` (i.e. `D ? ?`) with `D ~ D -> D`.
> [Hint: `1 -> 1 = 1` is of no use. Instead, first construct a solution `D ~ D -> ?^inf`
  ` (?^inf` the
> countably-infinite power of the universal domain `?)`, using the method of Exercise 8.23;
  note
> ` ?^inf x ?^inf ~ ?^inf`, so this reduces to a single fixed-point construction over
  `?`. Remark that
> ` ? ? D`, hence `D` is universal (and certainly non-trivial). Finally show `D x D ~ D`,
  and combine
> this with `D ~ D -> ?^inf` to conclude `D ~ D -> D`. Is `D` effectively given?]

## Following Scott's hint, step by step

1. **The "obvious" solution is trivial** (`Exercise825Unit.lean`). Solving `D ~ D -> V` by
  the
  fixed-point method starting at the *smallest* `V = ?` produces nothing: `
  funSpace_unitSys_isomorphic`
  proves `( ? -> ? ) ~ ?`, so the recursion is stuck at the trivial domain and never
  escapes it. This
  is why Scott says to change the method and start from ` ?^inf` instead.

2. **` ?^inf x ?^inf ~ ?^inf`** (`Exercise825Pow.lean`'s `pow_prod_isomorphic`,
  applied at ` ?`), so the
  two-variable equation `D ~ D -> ?^inf` collapses to a single self-map fixed point
  over ` ?`, matching
  Exercise 8.23's setup.

```

3. ****Solve $D \approx D \rightarrow ?^{\infty}$ inf $**$ (`\Exercise825FixedPoint.lean`). Concretely: $?^{\infty}$ inf $^{\infty}$ is effectively given** (Exercise 7.15), so Theorem 8.8(b) gives a projection pair $?^{\infty}$ inf $\Leftarrow ?^{\infty}$; composing it gives a finitary projection $c : ? \rightarrow ?^{\infty}$ with `\Fix(c)  $\approx$   $?^{\infty}$  inf  $^{\infty}$  (\fixedNbhd_cCombinator_isomorphic)`. The operator `t(a) := a  $\rightarrow$  c` (Definition 8.9's `\arrowComb (-) c`) is built as a genuinely continuous self-map `tOpMap c` of `\funSpace ? ?` (the technical heart of this file: a joint evaluator/double-curry construction from Table 5.5's combinators, `\toApproxMap_lamOp / \tOp_tOpMap`), sends finitary projections to finitary projections (`\ht_tOpMap`, via Proposition 8.10(b)), and Exercise 8.23's abstract machinery (`\isFinitaryProjection_fixOp`, `\fixedDomain_fixOp_iso_T`) hands us $D \approx D \rightarrow ?^{\infty}$ inf $^{\infty}$ for $D := \text{fixedNbhd}(\text{fixOp}(\text{tOpMap } c))$ (`\Dsol_isomorphic_funSpace_cCombinator`).

4. **** $?^{\infty}$ D , hence D is universal and non-trivial**** (`\Exercise825FixedPoint.lean`'s `\U_trianglelefteq_Dsol`). Chains `? ? ?^{\infty} inf $^{\infty}$ (\Exercise825Embed.lean's \trianglelefteq_iterSys, the "singleton stack" embedding), $?^{\infty}$ inf $\approx \text{fixedNbhd } c$, the general constant-function embedding $V ? (D \rightarrow V)$ for any domains D , V (\Exercise820.lean's \trianglelefteq_funSpace_const), and $D \rightarrow ?^{\infty}$ inf $\approx D$ (step 3, reversed). Since $?^{\infty}$ embeds as a genuine subdomain, D is certainly not the one-point domain -- non-trivial, and in fact universal (every countable domain embeds in $?^{\infty}$, hence in D).`

5. **** $D \times D \approx D$, and $D \approx D \rightarrow D$ **** (`\Exercise825Closing.lean`'s abstract closing argument, instantiated at $V := \text{fixedNbhd } c$ via `\hVV_cCombinator : (\text{fixedNbhd } c) \times (\text{fixedNbhd } c) \approx \text{fixedNbhd } c transported from step 2 along \fixedNbhd c  $\approx$   $?^{\infty}$  inf  $^{\infty}$ ). This is \exercise_8_25_main below, the answer to the exercise.`

Is D effectively given?

****Yes, but this is not formalized here**** -- matching this codebase's existing precedent for the *computability* clauses of the closely analogous Theorem 8.6 (`\sub`) and Exercise 8.23 (`\?t?`), both of which defer the same argument for the same reason (see `\Exercise823.lean`'s module `docstring`, Claim 3). The expected argument, informally:

- $?^{\infty}$ and $?^{\infty}$ inf $^{\infty}$ are both effectively given (`\U_isEffectivelyGiven`, `\iterSys_isEffectivelyGiven`), so Theorem 8.8(b)'s back-and-forth pair i, j witnessing $c := i \text{ comp } j$ is *computable* (`\theorem_8_8_b_strong`'s `\IsComputableMap` clauses, already proved).
- Definition 8.9's `\arrowComb` is built from `iArrow`/`jArrow`/`\curry`/`\evalMap`/`\prodMap`, all computable when their inputs are (routine, and already implicit in how `\Definition89.lean` builds these combinators from `\theorem_8_8_b_strong`'s computable witnesses); hence $a \mapsto a \rightarrow c$ is a computable operator whenever a is a computable finitary projection.
- By induction, every approximant `t.iterElem n` (`\Exercise823.lean`'s notation) is then computable (composition of computable maps is computable), and $?t? = \text{fix}(t) = \text{sqsup}_n t.\text{iterElem } n$ is a *recursively enumerable* union of computable approximants indexed by $n : \text{Nat}$ -- hence computable by the standard "effective limit of an effective chain" argument, the same style already carried out for the *other* effective limiting construction in this book (Theorem 8.8's `\Y_n--chain`,

```
`Theorem88b.lean`--`Theorem88m.lean`).
```

Carrying this out in Lean would require threading Definition 7.1's `ComputablePresentation` machinery through a directed union of presentations (one more layer than any single `ComputablePresentation` construction currently in this codebase provides) -- a standalone, comparably-sized follow-up effort, left undone here exactly as `Theorem86.lean`'s `sub` and `Exercise823.lean`'s `?t?` already are.

```
## Axiom footprint
```

```
`exercise_8_25_main` and `exercise_8_25_universal` both mention `?`, so -- like every other theorem in this codebase that does -- they inherit `?'`'s own `Classical.choice` footprint (#print axioms subseq {propext, Classical.choice, Quot.sound}), confirmed not new.

# Exercise 8.26 (Scott 1981, PRG-19) -- untyped `fun`-calculus in `?`, and translating typed
calculus back

> **Exercise 8.26.** Discuss in more detail the "pay-off" for `?`, namely the translation of
> "untyped" `fun`-calculus into `?` as shown by the equations at the end of the lecture after
the
```

```

> proof of 8.9. In particular show how the whole of the typed `fun`-calculus can be
  retranslated
> back into `? with the aid of projections. (Hint: whenever you want to write `f : D_a ->
  D_b`,
> write instead `f = b comp f comp a`, where `a, b` are finitary projections. Whenever you want
  to form a
> `fun`-abstraction `fun x{D_a}.sigma`, where `sigma` is of type `D_b`, instead form `fun x.
  b(sigma'[a(x)/x])`, where
> `sigma` is the further translation of `sigma` into untyped `fun`-calculus. Be sure to show
  that this
> result "has the right type" in the sense defined above.)

```

This is a genuinely **expository** exercise ("discuss in more detail"), unlike 8.17–8.25's crisp existence/uniqueness claims -- Scott is asking the reader to *unpack and verify* a translation scheme he has already sketched, not to discover new mathematics. The formalization below extracts the three pieces of that scheme that are actually checkable claims, and proves each:

- The end-of-lecture equations** (self-hosted application/abstraction): ``?` becomes its own model of untyped ``fun``-calculus once we fix ``i_ -> : (? -> ?) -> ?``, ``j_ -> : ? -> (? -> ?)`` (Definition 8.9). Application of one ``?`-element to another is ``u(x) := j_ -> (u)(x)`` (``Uapply``); abstraction of an "outside" function ``f : ? -> ?`` is ``fun x.f ~ = i_ -> (f)`` (``Ulam``). The content beyond bare notation is **faithfulness**: the self-hosted calculus computes the same thing as the outside one, ``Uapply (Ulam f) x = f(x)`` (``Uapply_Ulam``) -- i.e. ``b``-reduction inside ``?`'s internal ``fun``-calculus is sound, using exactly ``jArrow_comp_iArrow : j_ -> comp i_ -> = I``.
- The hint's translation recipe for ``fun``-abstraction, and "has the right type."** Generalizing away from ``?` to *any* neighbourhood system ``E`` and *any* retractions ``a, b : E -> E`` (in particular finitary projections, Definition 8.3): given the further-translated body ``body : E -> E`` (Scott's ``sigma``), the recipe ``fun x. b(sigma'[a(x)/x])`` is ``translateAbs a b body := b comp body comp a``, and it **always** satisfies the defining sandwich equation ``f = b comp f comp a`` (``translateAbs_sandwich``) -- this is exactly "has the right type," and needs nothing about ``body``'s own well-typedness, only idempotence of ``a``, ``b``. A one-line corollary (``translateApp_hasType``) checks the matching claim for **application**: if ``f = b comp f comp a`` and ``x`` already has type ``D_a`` (``a(x) = x``), then ``f(x)`` already has type ``D_b`` (``b(f(x)) = f(x)``).
- The correspondence ``f = b comp f comp a`` really does capture ``D_a -> D_b``.** This is *not* new content -- it is exactly Proposition 8.10(b)'s ``arrowComb_elementIso`/`finitaryProjection_arrowComb`` (``Proposition810b.lean``), which for finitary projections ``a, b`` produces ``(D_a -> D_b).Element ?o {f : ?.Element ? (a -> b)(f) = f}`` -- i.e. every ``g : D_a -> D_b`` *is* (uniquely) some ``f`` with ``f = b comp f comp a``, and conversely. We do not reprove this; we cite it as answering the hint's opening sentence directly.

What is deliberately out of scope. A full formal syntax + typing judgment for the typed ``fun``-calculus (variables, application, abstraction, a base-type context, substitution, and a structural induction assembling 1-3 above into "every typed term translates to an untyped one of the right type") is not built. The reason is the same one already used to defer the *effectiveness* clauses of Theorem 8.6/Exercise 8.23/Exercise 8.25: this project's convention is to formalize the mathematical content precisely (here: the two checkable claims 1-2, plus citing 3) while leaving

genuinely open-ended "build a term language and induct over it" scaffolding as prose discussion

,

since the payoff -- the induction is a routine unfolding of 1-3 at each syntax constructor,

with

``+`/` x ` cases following `->`'s pattern exactly (`sumComb`/`prodComb`'s own `IsRetraction`/`sandwich``

facts are already in ``Proposition810.lean``/``Proposition810b.lean``, so ``translateAbs_sandwich`` applies to *any* of the three combinators, not just ``->`` -- is not itself a new mathematical question. Scott's own hint stops at exactly this level of detail ("whenever you want to..."), i.e. a *recipe*, not a compiler; we formalize the recipe and its correctness.

Axiom audit: ``Uapply_Ulam`` mentions ``?``, hence inherits ``?``'s own ``Classical.choice`` footprint (``subseq`` ``{propext, Classical.choice, Quot.sound}``, not new). ``translateAbs_sandwich``/``translateApp_hasType`` are fully general (no mention of ``?``) and **choice-free** (``subseq`` ``{propext, Quot.sound}``).

-/

namespace Scott1980.Neighborhood

open NeighborhoodSystem ApproximableMap

/-! ## Part 1 (of the exercise write-up): the end-of-lecture equations, self-hosted in ``?`` -/

/-- **Self-application** inside ``?`` (the end-of-lecture equation ``u(x) := j_ -> (u)(x)``):

decode

``u`` : ``?`` into an actual function ``?`` `->` ``?`` via ``j_ ->`` (``jArrow``, Definition 8.9), then apply it to

``x``. -/

noncomputable def Uapply (u x : U.Element) : U.Element :=
 (evalMap U U).toElementMap (pair (jArrow.toElementMap u) x)

/-- **Self-abstraction** inside ``?`` (the end-of-lecture equation ``fun x.tau ~:= i_ -> (fun x.tau)``): given the

"outside" function ``f`` : ``?`` `->` ``?`` (``tau``'s ordinary denotation as an approximable map), encode it into

``?`` via ``i_ ->`` (``iArrow``, Definition 8.9). -/

noncomputable def Ulam (f : ApproximableMap U U) : U.Element :=
 iArrow.toElementMap (toFilter f)

/-- **Faithfulness** (``b``-soundness) of the self-hosted encoding. Applying the self-hosted abstraction of ``f`` recovers ``f`` itself: ``Uapply (Ulam f) x = f(x)``. The internal ``fun`` ``-`` calculus of

``?`` literally computes the same thing as the "outside" one it is modelling -- this is the actual

content of "the pay-off," beyond bare notation. Uses only ``jArrow_comp_iArrow`` : ``j_ ->`` ``comp i_ ->`` ``I`` (the

retraction half of Definition 8.9's fixed pair) and ``evalMap``'s defining equation (``evalMap_apply``). -/

theorem Uapply_Ulam (f : ApproximableMap U U) (x : U.Element) :
 Uapply (Ulam f) x = f.toElementMap x := by
 have hround : toApproxMap (toFilter f) = f := by
 have he := (funSpaceEquiv U U).apply_symm_apply f
 rwa [funSpaceEquiv_apply, funSpaceEquiv_symm_apply] at he
 unfold Uapply Ulam

 rw [h1, jArrow_comp_iArrow, toElementMap_idMap, evalMap_apply, hround]

/-! ## Part 2 (of the exercise write-up): the abstraction recipe, and "has the right type" -/

universe u

```

variable {a : Type u} {E : NeighborhoodSystem a}

/-- **Scott's translation recipe for a `fun`-abstraction**, `fun x^{D_a}.sigma`  $\mapsto$   $\text{fun } x. b(\text{sigma}[a(x)/x])$ : given
the further-translated body `body : E  $\rightarrow$  E` (Scott's `sigma`, the untyped realization of `sigma` as a
function of `x`), form the projection-sandwiched abstraction `b comp body comp a`. Stated for
an arbitrary
neighbourhood system `E` and arbitrary `a, b : E  $\rightarrow$  E` -- specializes to Scott's `?`/finitary
projections, but needs nothing special about `E`. -/
def translateAbs (a b body : ApproximableMap E E) : ApproximableMap E E :=
  b.comp (body.comp a)

/-- **Be sure to show that this result has the right type.** `translateAbs a b body` always
satisfies the defining sandwich equation `f = b comp f comp a` of Scott's `D_a  $\rightarrow$  D_b`
translation scheme
(the "sense defined above" -- see `Proposition810b.elementIsoOfProjectionPair`/
`arrowComb_elementIso`), **regardless of `body`** -- the only thing this uses is idempotence
of
`a` and `b` (true of every retraction, Definition 8.1, in particular every finitary projection,
Definition 8.3). Pure associativity + idempotence, mirroring the book's own one-line proof
(`(a x b) comp (a x b) = ... = a x b`, "Proposition 8.10's proof) transplanted to the
abstraction case. -/
theorem translateAbs_sandwich {a b body : ApproximableMap E E}
  (ha : IsRetraction a) (hb : IsRetraction b) :
  b.comp ((translateAbs a b body).comp a) = translateAbs a b body := by
  show b.comp ((b.comp (body.comp a)).comp a) = b.comp (body.comp a)
  rw [comp_assoc b (body.comp a) a, comp_assoc body a a, ha, <- comp_assoc b b (body.comp a),
    hb]

/-- **The matching claim for application**: if `f` already "has the right type" (`f = b comp f
comp a`) and
`x` already "has type `D_a`" (`a(x) = x`), then `f(x)` already "has type `D_b`" (`b(f(x)) = f(x)`).
Together with `translateAbs_sandwich`, this is the type-soundness invariant that both the
`fun`-abstraction and application clauses of the typed-to-untyped translation preserve. -/
theorem translateApp_hasType {a b f : ApproximableMap E E} (hsandwich : b.comp (f.comp a) = f)
  {x : E.Element} (hx : a.toElementMap x = x) :
  b.toElementMap (f.toElementMap x) = f.toElementMap x := by
  conv_rhs => rw [ <- hsandwich, toElementMap_comp, toElementMap_comp, hx]

/-- **A sanity check: the identity abstraction translates to the identity, and the recipe
applied
to `body = id` (the trivial "translation" of a bare variable `sigma = x`) already has the right
type
for free** -- `translateAbs a b (idMap E) = b comp a`, matching that a bare variable of type `
D_a` fed
through the `a`-then-`b` sandwich needs no further work. Included as a `0`-th case of the
induction discussed above (the base case: variables). -/
theorem translateAbs_idMap {a b : ApproximableMap E E} : translateAbs a b (idMap E) = b.comp a
:= by
  unfold translateAbs
  rw [idMap_comp]

# Exercise 8.27 (Scott 1981, PRG-19) -- Donahue's polymorphic/infinite products over `?`

> **Exercise 8.27.** (Suggested by James Donahue.) Finite cartesian products of domains are
  formed
> by the `D_0 x D_1`-construct we have used so often. The problem is to define -- computably
  -- some
> *infinite* cartesian products. In particular, as applied to the universal domain `?`, the
> combinator `sub` is to be regarded as a finitary projection of `?` whose fixed points are
> exactly *all* the finitary projections. A map `d = sub comp d comp sub` can be regarded as a
  *polymorphic
> type* (because, whenever `t` is a finitary projection (`=` type), then so is `d(t)`). The
> *continuous product* of *all* these types would be the domain of all approximable functions `
  x`
> such that `x(t) = d(t)(x(t))` for all types `t`. (Why does this equation mean that `x` is in
  the
> product?) Define `?` as a combinator by `? = fun d fun x fun t. sub(d(sub(t)))(x(sub(t)))`.
  Show that for
> `d` a polymorphic type, `?(d)` is a type. (Hint: it is easy to check that `?(d)` is a
  projection;
> the problem is to show it is finitary.)
```

This is the **last exercise in the entire book**.

What this file formalizes

```
**Step 1 -- `sub` regarded as a combinator on `?` itself.** Theorem 8.6's `sub : (E -> E) -> (E
-> E)`
(`Theorem86.lean`) is a per-map operation; Theorem 8.6(b) packages it as a genuine approximable
self-map `subApprox : (? -> ?) -> (? -> ?)`. To get "`sub` regarded as a finitary projection
*of* `?`"
(the exercise's own phrasing), we conjugate `subApprox` through the fixed pair `i_ -> : (? ->
?) -> ?`,
`j_ -> : ? -> (? -> ?)` (Definition 8.9) exactly as `Definition 8.9` itself builds `a -> b`
from `fun f.b comp f comp a` --
`subU := i_ -> comp subApprox comp j_ -> : ? -> ?`. We show `subU` is a genuine
finitary projection
(`isFinitaryProjection_subU`) whose fixed points are exactly the finitary projections of `?`
(`subUFixIso`, composed with Theorem 8.6(a)'s own `{f ? sub f=f} = ` finitary projections
characterization) -- a direct formalization of the exercise's opening sentence.

**Step 2 -- polymorphic types.** `IsPolymorphicType d := subU comp d comp subU = d`, Scott's `d
= sub comp d comp sub`.
The exercise's own justification ("whenever `t` is a finitary projection, then so is `d(t)`")
is
`polymorphicType_apply_mem_fix`: for `d` polymorphic and *any* `z` (not just a "type" `t`),
`d(z) in Fix(subU)`.
```

```
**Step 3 -- the `?` combinator.** Built by direct transcription of Scott's formula
`?(d)(x)(t) = sub(d(sub(t)))(x(sub(t)))` via `curry`/`evalMap`/`paired` (mirroring
`Exercise825FixedPoint.lean`'s `RMap` recipe), giving `piD d : (? -> ?) -> (? -> ?)`, then
conjugated
through `i_ -> , j_ ->` exactly as in Step 1 to land `piU d : ? -> ?` -- "`?(d)`, regarded
as living in
```

```

`?`,`" matching that "type" means a self-map *of `?`* (not of `? -> ?`).

**Step 4 -- "it is easy to check that `(d)` is a projection" (Scott's own hint).** Proved here
**unconditionally for every `d : ? -> ?`** (not just polymorphic `d`!) -- a genuinely easier
and
stronger fact than what Scott's theorem statement asks for, made possible because `?`'s own
formula *already* re-projects through `sub` at every occurrence of the bound type variable `t`
(`sub(d(sub(t)))`, not bare `d(sub(t))`): this makes the "type" fed to the application step
*automatically* a genuine finitary projection regardless of whether `d` itself is polymorphic
(`isFinitaryProjection_decode_subU`), which is exactly what both halves of the projection proof
need.

**Step 5 (Exercise 8.27(b)(0)) -- reduce "`piU d` is finitary" to "`piD d` is finitary."**
`piUFixIso : Fix(piU d) ?o Fix(piD d)`, built by literally copying Step 1's `subUFixIso` recipe
(`piU d = i_ -> comp (piD d) comp j_ -> ` has the same shape as `subU = i_ -> comp subApprox
comp j_ -> `). Packaged as
`isFinitary_piU_of_isFinitary_piD`, so the remaining work (Exercise 8.27(b)(1)-(b)(4), **not**
attempted here) is exactly to prove `IsFinitary (piD d)` for `d` polymorphic.

**"The problem is to show it is finitary" (Scott's own hint) -- the core content, deliberately
NOT
attempted.** See the discussion at the bottom of this file for why, and `HANDOFF.md`'s
2026-07-07
checkpoint for the planned proof route (Exercise 8.27(b)(1)-(b)(5), pivoting on Theorem 8.5's
step-closure formula rather than an ad hoc dependent-product construction).

Axiom audit: everything here mentions `?`, hence inherits `?`'s own `Classical.choice`
footprint
(`subseq {propext, Classical.choice, Quot.sound}`, not new).

  have h := toElementMap_mem_fix_of_isRetraction_sandwich isProjection_subU.1 (g := d) z
  rwa [hd] at h

/-! ## Step 4 (prerequisite): decoding `Fix(subU)` always yields a genuine finitary projection

The key fact behind "it is easy to check that `?(d)` is a projection" (Scott's own hint):
because
`subU` is idempotent, `subU(z)` in `Fix(subU)` for *any* `z` -- and `Fix(subU)` decodes, via `
j_ -> `, to
exactly the finitary projections of `?` (Step 1). Chaining these: `j_ -> (subU(z))`, viewed as
a map
of `?`, is *always* a genuine finitary projection, for *any* `z` at all, with no hypothesis on
`z`
or on how it arose. This is exactly what makes `?'s formula `sub(d(sub(t)))(-)` well-behaved
regardless of whether `d` itself is a polymorphic type. -/

/-- **Any `j_ -> `-decoded fixed point of `subU` is a finitary projection of `?'** -/

/#!/ ## Exercise 8.27(b)(1): reduce finitariness of `piD d` to Theorem 8.5's step-closure
formula

```

```

`Theorem85.lean`'s `isFinitaryProjection_of_formula` proves, for any approximable map `a : E
-> E`
on any neighbourhood system `E`, that Scott's step-closure formula (ii) --

`a(x) = {Y in E ? exists X in x, X subseq Y /\ X a X}`, for every `x in |E|`

-- by itself (no other hypothesis on `a`) implies `IsFinitaryProjection a`, with the witness
domain
`fixedNbhd a` built automatically from `a`'s own relation. Specializing `E := funSpace U U`,
`a := piD d` turns "prove `piD d` is finitary" into "prove `piD d` satisfies formula (ii)" --
no
external witness system to invent. This is exactly the reduction Exercise 8.27(b)(2)-(b)(3)
target;
what remains here is only to record the specialization and its corollary via Exercise 8.27(b)
(0). -/

/-- **Exercise 8.27(b)(1).** If `piD d` satisfies Scott's step-closure formula (ii), it is a
finitary projection -- a direct specialization of `Theorem85.lean`'s general
`isFinitaryProjection_of_formula`, no new proof needed beyond the specialization itself. -/
theorem isFinitaryProjection_piD_of_formula (d : ApproximableMap U U)
(hii : forall (x : (funSpace U U).Element) {Y}, ((piD d).toElementMap x).mem Y <=>
(funSpace U U).mem Y /\ exists X, x.mem X /\ X subseq Y /\ (piD d).rel X X) :
IsFinitaryProjection (piD d) :=
isFinitaryProjection_of_formula (piD d) hii

/-- **Exercise 8.27(b)(1), assembled with (b)(0):** formula (ii) for `piD d` alone gives
`IsFinitary (piU d)`, i.e. (combined with the already-Pass 8.27(a)) the entire exercise for `
d`
polymorphic. This pins down exactly what Exercise 8.27(b)(2)-(b)(3) need to supply: `hii`. -/
theorem isFinitary_piU_of_formula {d : ApproximableMap U U}
(hii : forall (x : (funSpace U U).Element) {Y}, ((piD d).toElementMap x).mem Y <=>
(funSpace U U).mem Y /\ exists X, x.mem X /\ X subseq Y /\ (piD d).rel X X) :
IsFinitary (piU d) :=
isFinitary_piU_of_isFinitary_piD (isFinitaryProjection_piD_of_formula d hii).2

/-! ## Exercise 8.27(b)(2): unwind `piD d`'s neighbourhood relation

`piD d = curry (piDUncurried d)` uses `FunctionSpace.lean`'s abstract `curry` (not the Ex
7.16/
Table 5.5 recursion-theoretic coded layer). Its general relation lemma curry_rel already
exists there:

`(curry g).rel X W <=> exists hX : V_0.mem X, (funSpace V_1 V_2).mem W /\ gSection g hX
in W`

reducing `(piD d).rel X W` to a literal set membership test `gSection (piDUncurried d) hX in
W`
of an actual map into the funSpace-nbhd `W` (no new proof needed -- `piD_rel_iff` below is the
direct specialization). The remaining unwinding is `gSection (piDUncurried d) hX`'s own
relation:
`gSection_rel` reduces it to `(piDUncurried d).rel (prodNbhd X Y) Z`, and rel_iff_mem_principal
(`Approximable.lean`) plus pair_principal_eq_principal_prodNbhd (Exercise821.lean,
general --
pairing two principal elements is the principal element of the product nbhd) convert that
into an
element-level statement, which the already-proven toElementMap_piDUncurried evaluates
in
closed form purely in terms of `subU`'s and `d`'s own `toElementMap` actions (built, in its own
proof, from `evalMap_apply`, `FunctionSpace.lean`'s abstract defining relation for `eval`).
This is
`gSection_piDUncurried_rel_iff` below -- the genuine content of this subgoal. -/

```

```

/-- **Exercise 8.27(b)(2)(a).** `(piD d).rel X W` reduces to a literal membership test -- the
    direct
specialization of `curry_rel` (`FunctionSpace.lean`), no new proof needed. -/
theorem piD_rel_iff (d : ApproximableMap U U) {X W : Set (ApproximableMap U U)} :
  (piD d).rel X W <=> exists hX : (funSpace U U).mem X, (funSpace U U).mem W /\
    gSection (piDUncurried d) hX in W :=
  curry_rel

/-- **Exercise 8.27(b)(2)(b).** `gSection (piDUncurried d) hX`'s own relation, fully unwound to
    a
closed elementwise formula in terms of the already-proven closed form `piDApply` (built, in its
own proof, purely from `subU`'s and `d`'s `toElementMap` actions plus `evalMap_apply`): reduce
via
`gSection_rel` to `(piDUncurried d).rel (prodNbhd X Y) Z`, then via `rel_iff_mem_principal` +
`pair_principal_eq_principal_prodNbhd` to the element pair `pair (principal hX) (principal hY)`,
then read off `toElementMap_piDUncurried`/`toElementMap_piDApply`. This is the "unwind `piD d`'s
neighbourhood relation" content of Exercise 8.27(b)(2). -/
theorem gSection_piDUncurried_rel_iff (d : ApproximableMap U U)
  {X : Set (ApproximableMap U U)} (hX : (funSpace U U).mem X) {Y Z : Set ?} (hY : U.mem Y) :

/-! ## Exercise 8.27(b)(3): formula (ii) for `piD d` -- substantial partial progress, not
    closed

**The reduction is complete and clean.** Via `Sub8_6.toFilter_toApproxMap`/`mem_toFilter`
(`mem_iff_mem_toApproxMap`) plus the already-proven `toApproxMap_toElementMap_piD`, `hii`'s LHS
`((piD d).toElementMap x).mem Y` reduces *exactly* to a literal membership test
`piDApply d (toApproxMap x) in Y` (`piD_toElementMap_mem_iff`) -- no abstract "element"
reasoning
left, purely a statement about the actual map `piDApply d (toApproxMap x) : ApproximableMap U U`
and the actual set `Y`.

**The `?` half closes unconditionally**, via `Theorem85.lean`'s newly-extracted
`mem_of_exists_rel_self` (isolated from `isFinitaryProjection_of_formula`'s own proof, valid
for
*any* `a : E -> E` with no hypothesis) -- `hii_easy_direction` below.

**The `?` half (the genuine mathematical content) is *not* closed here.** Attempting it exposed
a
precise, previously-undocumented obstruction, recorded in full in `HANDOFF.md`'s 2026-07-07
checkpoint: given `f := piDApply d (toApproxMap x) in Y` (`Y = stepFun [(Y_i, Z_i)]_i`),
unwinding
each `f.rel Y_i Z_i` via `gSection_piDUncurried_rel_iff`/`toElementMap_piDApply` and Theorem
8.5's
*already-proven* formula (ii) for `subU` (Exercise 8.27(a)) and for each per-`i` "type"

```

```

    projection
`P_i := toApproxMap(jArrow.toElementMap(subU.toElementMap(d.toElementMap t_i)))`
(`isFinitaryProjection_decode_subU`, `t_i := subU.toElementMap (U.principal hY_i)` produces
per-component witnesses `W_i` (`W_i` subseq Z_i, `P_i.rel W_i W_i`) -- the natural next
step is to
assemble `X := stepFun [(T_i,W_i)]_i` for domain-side nbhds `T_i` supseq Y_i with `t_i.mem
T_i`
(continuity), to get `x.mem X` and `X` subseq Y. But testing `(piD d).rel X X` itself re-
runs the same
unwinding *at `X`'s own `T_i`, which feeds `s_i := subU.toElementMap (U.principal hT_i)` -- **
not**
`t_i` -- into `d`, landing on a *different* type-projection `P_i' := toApproxMap(jArrow.
toElementMap
(subU.toElementMap (d.toElementMap s_i)))`. Since `T_i` supseq Y_i is unavoidable (needed
for `X` subseq Y`
by `mono`), `s_i <= t_i` is forced (monotonicity), so `P_i' <= P_i` is generally a *
strictly weaker*
map, and `P_i.rel W_i W_i` does not transfer to `P_i'.rel W_i W_i` for free -- the self-
relation
witness and the continuity witness pull `T_i` in incompatible directions with a single round of
formula (ii). The likely resolution (not attempted) mirrors `Theorem85.lean`'s *own* `(i) ? (ii
)`
hard direction (`exists_principal_eq_of_isRetraction_le_idMap`'s compactness-reflection
argument,
~200 lines) rather than a single formula(ii)-chase: an iterative/compactness "descent" building
`T_i` as a directed limit that becomes self-consistent *in the limit*, using algebraicity
(`eq_iSupDirected_principal`) to show the descent stabilizes at a genuine finite/principal nbhd
--
a comparably-sized undertaking to Theorem 8.5's hard direction, not a quick corollary of it. `d
`s
polymorphism (`IsPolymorphicType`, unused so far) is expected to enter here, but exactly how is
not
yet worked out. -/

/-- **Exercise 8.27(b)(3)(a).** `hii`'s LHS, reduced to a literal membership test: no abstract

/-! ## Exercise 8.27(b)(3)(b): the `?` half of formula (ii), closed

**Resolution of the obstruction documented above.** The fix: instead of chasing a *single*
domain
witness `T_i` supseq Y_i (which forces the wrong type-projection `P_i` via `s_i <= t_i`)
, observe that
`t_i` is *itself* the directed sup of its own `subU`-self-consistent approximants
(`eq_iSupDirected_scPrincipal`) -- a family on which `principal T = subU(principal T)` *exactly

```

```

*
(`subU_principal_eq_of_rel_self`, by antisymmetry: ` <= ` from `subU`'s projection property, `
  >= ` from
self-consistency). Since `d`, `subU`, `jArrow` are all continuous, the "type at `t_i`" `P_i` is
*itself* the directed sup (in the `ApproximableMap` order) of the "type at `T`" `P_T` over this
  same
family, so `P_i.rel W W` (already established) is, by directed-sup compactness
(`toApproxMap_rel_iSupDirected`/`mem_iSupDirected`), *already* witnessed at some single
self-consistent `T` in `(t_i)`. A second application of the same compactness fact (this time
  to the
continuity witness for `x`) and one directed-family common refinement (`scFamily_directed`)
  then
finds a *single* `T` simultaneously self-consistent, `x`-continuous, and `P_T`-self-relating --
  the
correct `T_i`. Notably, this argument uses only `subU`'s algebraicity/continuity and
`isFinitaryProjection_decode_subU` (Step 4, unconditional); **`d`'s polymorphism is never used
  **, so
the result below holds for *every* `d`, polymorphic or not -- a strictly stronger and more
  uniform
fact than Scott's exercise statement requires. -/

/-- **`subU`'s self-relating neighbourhoods are exactly fixed under `principal`.** If `subU.rel
  T T`,
the "witnessing element" `T` is *exactly* fixed by `subU` (not merely approximated): ` <= ` is
`subU`'s projection property (`subU <= I`), ` >= ` is `principal_le_of_mem` applied to the
  membership
`subU.rel T T` gives via `rel_iff_mem_principal`. -/

/-- **Exercise 8.27(b)(3)(b), single-pair case -- the genuine mathematical content.** Given
`f := piDApply d (toApproxMap x)` relates `Y_0` to `Z_0`, produce `X` (a single `step`) with
`x.mem X`, `X subseq step Y_0 Z_0`, `(piD d).rel X X`.

The compactness-descent argument, in outline (`t := subU(Y_0)`):
1. Formula (ii) for the finitary projection `piDType d t` (at `t`'s own image of `x`) gives `W
  subseq Z_0`
  with `piDType d t` self-relating `W`.
2. Both `(toApproxMap x).rel _ W`'s witness and `(piDType d t).rel W W` are pushed down, via
  `t = bigcup scPrincipal` and directed-sup compactness, to some self-consistent
  approximants
  `i_0, i_1 in scFamily t`.
3. A common refinement `k` (directedness of `scFamily t`) makes both facts hold
  simultaneously at
  `T := k.1`: `(toApproxMap x).rel T W` (monotonicity) and `(piDType d (scPrincipal k)).rel W
  W`
  (monotonicity of `piDType d`, since bigger domain element  $\Rightarrow$  bigger map).
4. `scPrincipal k` is exactly `subU`-fixed (self-consistency), so `piDType d (scPrincipal k)`
  is
  exactly the type-projection `X`'s own self-test uses at `T` -- no mismatch. -/

/-! ## Discussion: "why does this equation mean that `x` is in the product?"

Scott's parenthetical question, about `x(t) = d(t)(x(t))` (all `t`): unwind the right-hand side
using Exercise 8.26's `Uapply`/`Ulam` (the self-hosted application of an element of `?`
regarded
as a "type"): `d(t)(x(t))` means `Uapply (d.toElementMap t) (x.toElementMap t)`, i.e. *decode*
`d(t)` via `j_ ->` into an actual map `D_{d(t)} : ? -> ?` and apply it to `x(t)`. Since `d`
is a
polymorphic type, `d(t)` in `Fix(subU)` for every `t` (`polymorphicType_apply_mem_fix`), hence
`D_{d(t)}` is *always* a genuine finitary projection -- "the type at `t`" in the informal
reading.
The equation `x(t) = D_{d(t)}(x(t))` is then exactly the defining property of being a **fixed
point** of that projection, i.e. `x(t)` in `Fix(D_{d(t)})`. Since `Fix` of a finitary
projection is
(order-isomorphic to) a genuine domain, this says precisely: *`x(t)` is a legitimate element of
the domain named by the type `t`*, for *every* type `t` simultaneously -- i.e. `x` is a
dependent
family `x : ?_{t : Type} D_{d(t)}`, a bona fide element of the "continuous product." Nothing
about
this needs a separate Lean lemma beyond what is already proved above; it is genuinely just
Scott
inviting the reader to notice that his equation *is* the universal-domain encoding of dependent
```

products (a form of impredicative/parametric polymorphism, a la System F).

Why "the problem is to show it is finitary" is left unattempted here

Scott's own hint stops at "it is easy to check that $\pi(d)$ is a projection" -- established above,
in fact unconditionally, for *every* d . For the finitary half he gives *no* technique at all
****,
unlike literally every other exercise/theorem in this book (which come with a concrete "(Hint: ...)" naming a specific construction or reduction). This is deliberate: Exercise 8.27 is the ***last* exercise in the book****, credited to a named correspondent (James Donahue), and is posed as
a genuinely open-ended research problem about a *dependent/polymorphic* product -- Scott is asking the reader to discover a construction, not recalling one.

Concretely, every "finitary-closure" result proved elsewhere in this project
(`finitaryProjection_arrowComb`, `_prodComb`, `_sumComb` in `Proposition810b.lean`; Theorem 8.6(b)'s
own `isFinitary_subApprox`) works by exhibiting `Fix` of the projection in question as order-isomorphic to an *already available* domain (a product/sum/function-space/subsystem-space built from *fixed*, finitely many ingredient domains). `Fix(piD d)` has no such ready-made candidate: it is the dependent product $\prod_{t : T} \text{Fix}(D_{\{d(t)\}})$ ranging over a *continuum* of "index" values t , indexed by a domain (T) rather than a finite/discrete set, with the fibers
`Fix(D_{d(t)})` themselves varying (dependently, via d) rather than staying fixed.
Constructing a
"domain of dependent-continuous-sections" and proving `Fix(piD d)` is isomorphic to it is a genuinely new piece of domain theory (closer to a logical-relations/realizability argument for System-F-style parametric polymorphism than to any single-step algebraic closure fact), with no template anywhere in Lectures I-VIII. It is intentionally left as the natural terminus of this formalization project, matching Scott's own framing of it as "the problem."
-/
